In seeking means for improving an associated ailment the author has developed a therapy for conditions which surpass the original goal in importance.¹ This new therapy consists essentially in administering four insoluble chemicals which are widely used separately and in various combinations with each other and with different medicaments in gastrointestinal disorders. When the daily dosage of each chemical is individually adapted there consistently follows improvement or subsidence in the manifestations of degenerative processes.

For some time it was not apparent why such benefits should follow this medication. It was early evident though that a special laxative action was developed, and its character suggested that it was probably due to the enhanced proliferation of some organism constantly present in the adult intestine. There were other special clinical responses. These were interpreted as supporting the theory of a modified intestinal flora. These additional responses would sooner or later become so disturbing to most patients that a special chemical was used for their prevention.

After the medication was thus developed a bacteriological study was made by Dr. John T. Myers of this city.¹ The essentials of some of his findings have been previously published, but their importance calls for repetition. Based upon these findings and personal clinical observations, authoritative theories are hereinafter outlined which explain how the therapy suggested may so modify the intestinal flora and its products that there consistently results diminished activity of *B. coli* in intestinal putrefaction, and subsequently improvement or subsidence in the manifestation of degenerative processes.

Special Laxative Action

When colloidal aluminum silicate and

an insoluble preparation of bismuth are given for a sufficient length of time and in the absence of decisive pathology, a laxative action of the bowel is induced. Properly adjusted in both dosage and formula, this laxative action is unusually effective and the stool becomes soft, well-formed, and nearly deodorized. The various relations of the laxative action to the therapy will be discussed in different sections of this article. Preceding and accompanying the laxative action is a modification of the intestinal flora.

Special Clinical Bacteriology

A demonstrable modification of the flora is reduction in the percentage of colonies that produce the metallic sheen which is typical of the colon group on Levine's eosin methylene blue media, as shown by Meyers.¹

In normal subjects and in patients before treatment fecal culture usually showed that less than six per cent of such colonies were unsheened. In patients under treatment whose bowels were not loose *a priori*, after the special laxative action had been established the numbers of such unsheened colonies usually ranged from seventy to ninety-eight per cent, and in an intermediate time the percentage was an intermediate number but varying in different patients, thereby indicating that there is a progressive development in the loss of sheen-producing power. These unsheened colonies responded positive to methyl red tests and negative to Voges-Proskauer, thereby establishing their identity as colon bacilli.

After the laxative action had been established, fecal cultures showed an increased percentage of colon bacilli over that found before treatment. This increase usually ranged from ten to thirty per cent.

ried forward underneath the free hump down to and in front of the anterior border of the septum, just behind the posterior border of the columella. This incision is extended to the anterior nasal spine. The hump is grasped with forceps and taken out. The resulting rough and jagged edges of the nasal bones are filed smoothly down with a rasp.

The next step is to create another subperiosteal channel on either side along the maxillonasal groove with a periosteal elevator. A groove director is inserted at the opening of this subperiosteal channel and a right-angle saw is gently inserted and placed in line with the maxillonasal groove. This saw is guided by the left free hand on the outside. Then by the same up and down movement the bone is severed along this line. The same

process is repeated on the opposite side. After the sawing is completed the bones are fractured inwardly by digital pressure exerted on the outside. The nose immediately becomes narrower and the gap created by the removal of the hump is now closed up by the approximation of the mobile, fractured nasal bones. The lower borders of the lateral cartilages now protrude prominently into the cavity and must be clipped in proportion to the shortening of the nose. The tip may or may not be corrected depending on its esthetic appearance. The columella is sutured to the septum in its new position with heavy black silk suture. A dental stent is applied to the nose. The stent and the suture are removed on the seventh day.

1021 PARK AVE.

TRANSFER OF TUMOR CELLS BY SURGICAL KNIFE

For years, on empirical grounds, all careful surgeons, have discarded, to be sterilized, instruments with which they have cut into malignant tissue, rather than continuing to use those same instruments in operative procedures when incising adjacent health tissue. This is particularly true in relation to biopsy and subsequent radical surgical treatment.

A careful study of the blades of knives used for incision, not only of tumor tissue but of apparently healthy tissue in the immediate vicinity of the tumor tissue, has shown that malignant cells are frequently adherent to the blades, says *The New England Journal of Medicine*. Saphir*, who carried on this study, has made direct smears from the blades of the knives, or washed them in saline and made smears from the saline suspensions. In every instance, smears made from knives that had cut through tumor tissue showed the presence of tumor cells, occasionally in very large numbers. At times, smears made from material on a knife used for excision of a nodule for biopsy revealed the presence of tumor cells, even though there was no gross evidence of tumor in the tissue traversed by the scalpel. Staining reactions indicated that these tumor cells were viable and, therefore, a definite source of danger. While not every tumor cell transplanted to

a new site is capable of growth, nevertheless, the danger is a real one and may explain certain of the recurrences in the surgical scar when apparently satisfactory excision had been done so far as removal of the tumor was concerned.

The added procedure of changing the instruments is so slight and is already in such general use that even a potential rather than an actual danger should be sufficient for every surgeon to insist on its being rigidly carried out.

CONFERENCE ON GOITER

The annual meeting of the American Association for the Study of Goiter will be held in Detroit, with headquarters at the Book-Cadillac Hotel, on June 14-16. A distinguished array of speakers is announced.

When John Lewis gets a little leisure we must have him organize the medical profession on an eight hour basis. Our rights have been trampled on for ages.—*Nebraska State Medical Journal*

The primary purpose of all medical organizations is to provide a high grade of service and to prevent exploitations of the sick of a community by charlatans.—C G Heyd, M D

*Saphir, O. *Surg Gyn & Obst* 63 775 1936

is the colon bacillus Herter⁷ described a colon bacillus diarrhea in which there are greatly increased numbers of *B coli* in the feces, with "no increase in virulence on the part of the bacilli"

Jordan's deduction makes possible a scientific explanation of how the proposed medicant, which Meyers has shown enhances the proliferation of *B coli* *in vitro*, and during the clinical use of which he has found in fecal cultures an increase in the number of colon bacilli, may induce a laxative action, or, when the medicant is excessive, a diarrhea. That the aluminum-bismuth combination does induce a laxative action is corroborated by Antoine and Rolland⁸ and other authors

Special Clinical Responses to Aluminum-Bismuth Combination

The special clinical responses to the aluminum-bismuth combination in addition to the laxative effect, might in part be explained by the *in vitro* action of *B coli* previously mentioned, i.e. an elaboration within the intestine of substances which are acidific, irritative, and absorbable, but varying in their manifestations in different patients. Pruritus ani, local dermatitis, and aggravation of chronic colitis appear to be clinical responses to local irritation. A decrease in the pH of the stool appears to be a fecal consequence to an increase in intestinal acid. Pain and tenderness in various tissues throughout the body—an aggravation of the previously developed degenerative processes, with articular pain in addition at times—appear to be clinical responses to the absorption of irritating substances. If the dosage of the aluminum-bismuth combination is further increased so that there is a distinct looseness of the bowel, these undesirable responses in susceptible patients may be overwhelming. There is sometimes wide variation in individual responses to only slight changes in the medication.

Special Clinical Responses to Neutralizing Chemical with the Aluminum-Bismuth Combination

After the special laxative action has

been developed one of the chemicals that may be administered to neutralize the irritating substances within the intestine is calcium carbonate⁹. As has been previously noted, this is the chemical used in the laboratory to neutralize the acid elaboration of *B coli* in sugar fermentation. Calcium carbonate is insoluble and nonabsorbable, so whatever substances it neutralizes clinically must be within the intestine. Of course, some metabolic products may be buffered with this insoluble chemical, but the clinical responses indicate that the major neutralization and adsorption are with products that are more purely acid, such as occurs with an enhanced proliferation of *B coli* in sugar fermentation and termed "irritant acids and gas" by Jordan. The pH of the stool increased with this neutralization.

When calcium carbonate was administered so as to be mingled with these adventitious products, subsidence or improvement was consistently observed in the symptoms or scientific findings of the following degenerative processes, chronic colitis, osteoarthritis, neuritis, myalgia, arteriosclerosis, angina pectoris, hypertension, keratitis, conjunctivitis, glaucoma, incipient nephritis, and some types of periodical headache. The initial intestinal condition is considered to be enhanced proliferation of putrefactive bacteria. Colitis is believed to be in the usual early sequence. No attempt has been made to explore the whole field of degenerative processes that are responsive to this special chemical therapy. Brief case reports illustrative of some of the degenerative processes of which the manifestations have been observed to be favorably and consistently affected, were given in the preliminary report¹.

Corroboration by Comparative Effects of Colon Bacillus Vaccine

The use of colon bacillus vaccine by Mateer et al from which they report favorable responses in chronic colitis and some associated conditions tends to corroborate our fundamental propositions.

1 Various degenerative processes may be caused by the colon bacillus in an environment of sufficient putrefactive organisms

Special *in vitro* Bacteriology

Cultures of whole fecal flora were inoculated into a tube of dextrose broth and into another such tube to which 0.5 per cent of the medicament had been added. Transfers were made at different intervals from these tubes. Plates were made on EMB medium at each transfer. The results are given in Table I.

When the cultures were left standing four days those containing the medicament were viable while those in the control had died, and after being cultured for two weeks in the presence of the medicament the colon bacilli were still living. When the culture period was two to four days there was no change shown in the sheen-producing power, but when

ments more sugar. That is, these acid elaborations, according to concentration, impair or stop the fermentation of sugar by the colon group.²

Diversion of *B. coli* Activity

Jordan³ says, "Colon bacilli of human origin are practically devoid of power to dissolve and peptonize native proteids such as casein and egg-albumin. It is therefore only in the presence of putrefactive anaerobes or other bacteria capable of peptonizing proteids that colon bacilli aid in excessive intestinal putrefaction." *The enhanced proliferation of B. coli tends to suppress putrefactive organisms.* "Its possible antagonism to certain putrefactive bacteria, a fact which

TABLE I.—PERCENTAGES OF TYPE OF COLONIES OF EMB PLATE WITH WHOLE FECAL FLORA

cultured for two weeks in the presence of the medicament there were large numbers of unsheened colonies. These unsheened colonies on further tests proved to be colon bacilli.

Colon Bacillus Elaborations in the Laboratory

In the test tube, *B. coli*, in the presence of carbohydrate and protein, elaborates numerous acids and various metabolic products. Some of these elaborations may be irritative and absorbable. The amount and character of part of these irritative products depend upon the specific fecal flora used in the tests. That is, some of the irritative and absorbable bacterial elaborations will depend upon the difference in intestinal environment of each patient to which these bacterial floras are exposed.

Ford states that calcium carbonate is used to neutralize the acids elaborated in the fermentation of sugar by *B. coli*. And when these products of this group of organisms are so neutralized it fer-

has been demonstrated in interesting studies by Bienstock and Tissier and Martelly⁴ is considered by Zinsser and Bayne-Jones⁴ to be one of the most important functions of the colon bacillus. Park and Williams⁵ also say that members of the colon group act antagonistically to many of the proteolytic bacteria in the intestinal tract, thereby inhibiting putrefactive processes.

Since *B. coli* does not initiate proteolysis, the suppression of putrefactive organisms by its enhanced proliferation diverts *B. coli* to fermentative activity, thereby lessening its elaborations in putrefactive processes and increasing its elaborations in sugar fermentation. "Excessive sugar fermentation by *B. coli* with liberation of irritant acids and gas," Jordan says, may cause "diarrhea."³ The report of Mateer et al.⁶ on the beneficial effect of colon bacillus vaccine in "chronic functional diarrhea" seems to support Jordan's deduction. For the only bacteriological finding in "diarrhea" mentioned by these investigators

while enemas, additional magnesium hydroxide, or other mild laxative is given as a supplement. Occasionally the above dosages are increased.

After the laxative action is developed calcium carbonate is administered daily in such an amount as will neutralize the adventitious intestinal products then elaborated. The amount required has usually ranged from 0.7 to 2.5 grams, it being an individual adjustment. Too much calcium impairs the effectiveness of the laxative action and apparently irritates the intestinal mucosa.

Since the chemicals are administered over long periods of time there must be a finer individual adjustment of dosages than is required in short periods of use. For various reasons, changes develop from time to time in dosage requirements.⁹

After the laxative action is developed an adjustment is made in the dosage of the aluminum or bismuth preparation unless the maximum amount of each is required to maintain the laxative action. Since the laxative effect from the viewpoint of technic is produced by the combined actions of bismuth and aluminum silicate, the dose of one of these preparations (usually the bismuth) is reduced and used as the variant in controlling the laxative action and the full desired daily amount of the other given. This often is preferable to reducing the dose of both of these preparations, because there usually is need of more sedative effect upon the intestinal mucosa than is secured by proportionally reducing the dose of both.

When the bowel is loose *a priori* either the bismuth or aluminum silicate must be given in reduced dosage from the beginning. In this class of cases, calcium carbonate is given at the beginning of medication.

To suspend the chemicals when they are added by the patient to fluid, about one-twelfth of the total mixture by weight should be powdered acacia, for flavoring, one-eighth may be sucrose. The mixture will roughly have a volume that is double the weight. A small medicine glass graduated in cubic centimeters and

drams is used by the patient in measuring each dose of the powder.

The composite medicament is usually directed to be taken in a glass of hot water on first arising and some interval before breakfast, or on retiring and two or three hours after food, or in divided doses at these times. If there is an excess of hydrochloric acid it should be taken at the proper interval after meals to neutralize the excess of this acid.

After the laxative action is established the medicament is directed to be taken in the minimum amount required to produce a stool that is soft but well-formed. Looseness of the bowel must be avoided. This requires a constant cooperation on the part of the patient in adjusting the daily dose to the proper laxative effect.

Diet

A liberalized, well-balanced, smooth diet with abundance of mineral and vitamins is prescribed. Fruit juices are freely permitted, with a proper interval from the medication. Acidulous or cultured milk is excluded. Patients who previously have had cultures of the acidophilus group implanted or colonies developed by diet may redevelop such colonies while under this medication with only a moderate daily amount of milk. The elaboration of acid within the intestine by such organisms seriously interferes with the proposed therapy. For one of the essentials in this colon bacillus chemical therapy is neutralization of intestinal acid¹—the antithesis in this respect to the Metchnikoff treatment.¹⁰

Summary in Order of Sequence

- 1 Aluminum-bismuth combination enhances proliferation of *B. coli*.

- 2 Suppression of proteolytic bacteria and consequent reduction in metabolic products elaborated by *B. coli* fermentative activity of *B. coli* increased.

- 3 "Excessive sugar fermentation by *B. coli*" "liberation of irritant acids and gas" "diarrhea," or mild laxative action when aluminum-bismuth combination is properly controlled.

- 4 Manifestations of local irritation (aggravated colitis, pruritus ani, derma

2 The chemical therapy suggested modifies the intestinal flora and more particularly the colon bacillus and its elaborations thereby favorably affecting the manifestation of degenerative processes

General Effects of Vaccine

A stock colon bacillus vaccine was used by Mateer et al.⁶ They report favorable results in chronic colitis, chronic functional diarrhea, colon distress, spastic constipation, and associated chronic headache and toxic vertigo. They further add

Side Effects

"Aside from the effects noted above, B coli vaccine therapy has been noted to have certain important and gratifying side effects. These occur much too frequently, when vaccine therapy is employed to be explained as a mere coincidence. Many of these patients report a striking improvement in their general feeling of well being, such as they have not noted in many years. This subjective relief is often reflected in their general appearance, increased appetite, and in some cases, in increase in weight."

In the chemical therapy the "side effects" have been previously reported as improvement in appetite, digestion, and nutrition lessened flatulence, pink color of skin, lessened irritability, improved reaction time, more optimistic psychology, and markedly improved vitality.¹

Limitations

Mateer et al. say, "The most important limitation rests on the observation that the desirable therapeutic effects obtained are not permanent. If one gives a single course of vaccine therapy, with no follow-up injections, after four to twelve months numerous patients note the good effect of the vaccine 'wearing off.'" So in some cases "advice has been given to avoid subsequent loss of the vaccine effect, by obtaining a single vaccine injection about once a month."

In the colon bacillus chemical therapy also the symptoms usually return but sooner after discontinuance of the medicament.¹ Therefore it has usually been recommended that this chemical therapy be continued over long periods of time

and it has been so used (more than six years in some cases) with no detrimental effect detected

Mateer et al. further say "In cases with no evidence of an arthritic tendency, or rare occasions, following a B coli vaccine injection, slight joint pain, lasting a day or two, has been encountered. In such cases vaccine therapy has been discontinued at this point."

In the chemical therapy the same effect sometimes follows overdosage of the laxative agents or underdosage of the neutralizing agent. Proper adjustment of the dosage of the different chemicals corrects the undesirable effect, and the therapy is continued.

In the colon bacillus vaccine therapy an overdose of the vaccine is followed by looseness of the bowel, just as occurs in the chemical therapy with an overdose of the medicament.

While there is no proof of the mechanism which induces these similarities of effects it is possible that the enhanced proliferation of colon bacilli that follows the medication may produce autovaccination due to the increased liberation and absorption of bacterial proteins as a result of enhanced bacteriolysis. Some of the theories advanced concerning changes induced in the intestinal flora may not prove to be valid, yet this in no wise detracts from the observation that manifestation of improvement in various degenerative processes consistently follows the therapy proposed.

Technic of Medication

If the bowel is constipated and not subject to periods of looseness the usual practice is to administer daily 13 grams bismuth subcarbonate and about three grams of colloidal aluminum silicate (kaolin). The aluminum silicate is potentiated with about twenty per cent of an insoluble hydroxide. Aluminum silicate is then effective in smaller amounts. Magnesium hydroxide is used when the bowel is constipated, aluminum hydroxide when the bowel is loose.

This dosage is continued until the special laxative action is developed. The time required for this development varies from a few days to several months. Mean-

WHO IS RESPONSIBLE?

Who is responsible for making maternity safe? The obligation rests firmly upon four groups, Dr George W Kosmak said in a recent address before a mass meeting on maternity care in Rochester, N Y—the husband and wife, the physician, the nurse and midwife, and the general public

"It is easy to understand why husbands and wives seek a physician who can provide a simple, easy, painless childbirth," he said "Often a nervous, emotional woman will demand that her physician promise to give her anesthesia so that she will be relieved of all pain, and these appeals are sometimes difficult to resist Prospective parents, however, should realize that every physician will do all in his power, within the realm of safety, to ease the pain of childbirth but that certain routine efforts to relieve pain tend to increase the need for operative interference and to multiply the danger of infection and other complications"

When our American women started to go to hospitals in increasing numbers to have their babies, this was held as a solution to the problem of high maternal death rates, according to Dr Kosmak It was generally assumed that the hospital is safer than the home "But there is abundant evidence," he said, "that hospital confinements are not necessarily safe confinements, and in fact that the degree of safety varies as the hospitals and their attendants vary in competence The doctor selected by the prospective mother and father assumes a great responsibility His attentions should begin in the early months of pregnancy and before the time for labor comes He should know whether this is likely to be normal or difficult A certain proportion of accidents are unavoidable but these have been shown to be small in number compared with those complications which may be attributed to carelessness in unskilled and untimely inter-

ference by the physician and in improper environment

"The physician should be ready for unexpected accidents and abnormalities Many of these can be recognized long before delivery This may require skill but if it is exercised at an early time will often prevent untoward consequences I have every confidence that in the future the skill and standing of an obstetric attendant will be judged less by his operative dexterity than by his ability to conduct a labor in accordance with the normal mechanisms of this process, unless specific indications warrant interference

"It is a great satisfaction to record that the medical profession is accepting more fully the responsibility for improving conditions," he continued "Physicians in high standing in many places are devoting a great deal of their time to looking into the cause of maternal deaths in their communities and are actively directing efforts to improve available maternity facilities

"If the public and the medical profession were to encourage adequate education for nurses and midwives so that they could do in this country what they do in many foreign countries with death rates less than ours, some of the difficulties in improving maternity would disappear If properly educated, experienced and supervised the midwife could act as a valuable assistant to the physician in all normal cases"

It is only when an aroused and interested community begins to ask questions, Dr Kosmak thinks, that proper attention will be given to improving maternity care "I firmly believe that an inventory by the community of its obstetrical facilities will do much to engender a spirit of cooperation between those most closely interested—the prospective mother, her attending physician and the nurse"

ULCERATIONS OF THE NASAL MEMBRANES AND PERFORATION OF THE SEPTUM IN A COPPERPLATING FACTORY

Unusual and Sudden Incidence

MICHAEL H BARSKY, M D , *New York City*

Ulcerations of the mucous membranes and perforation of the nasal septum associated with the use of chromium and chromium compounds in industry have been recognized for some time

The literature contains no reference to such nasal disorders related to copperplating and it seems desirable to place on record the following occurrence

In March 1936 two employees of a copperplating establishment reported at our office for treatment of infected abrasions of the hands, and peculiarly enough, it was noted that both were suffering from acute coryza. When questioned concerning upper respiratory ailments both complained of persistent running nose, nasal bleeding and nasal obstruction, all of which were of recent origin. Further, they volunteered the statement that many of their coworkers suffered from similar complaints.

Nasal examinations of these two men revealed the presence of shallow ulcerations of the nasal septum and turbinates. As a result of these unusual findings, all of the employees of the plating department of this establishment were examined and a hygienic and environmental study of the premises conducted.

Description of Plant

The factory was engaged in the manufacture of pocketbook frames and similar sundries. It was situated in an old loft building and occupied the entire sixth floor, an area of 40,000 square feet. A space in the northwest corner measuring seventy-five by fifty feet was set aside as the plating department. Its northern wall was solid brick. The west wall, also brick, faced the river and contained eight windows of usual size and construction. The south and east walls consisted of three-quarter inch pine boards

with rather large unprotected openings serving for ingress and egress. In this room were, five bronze plating tanks, four nickel-plating tanks, one large acid (hard) copperplating tank and four soft copperplating tanks, tumbling barrels, storage crocks containing copper, bronze, and nickel solutions, crocks of potash and soda solutions, acids, etc. A small section ten by fifteen feet in the northwest corner of the plating department was partitioned off by three-quarter inch pine boards and served as the acid room. The arrangement of the tanks is shown in the floor plan (Fig 1).

Chemicals Used and Plating Technic

All the plating tanks were approximately 300 gallon capacity, except for the considerably larger acid copper tank. The solution contained in the copper tanks was composed of eight ounces of copper cyanide and eight ounces of sodium cyanide to each gallon of water, in the bronze tank, six ounces of copper cyanide, six ounces of sodium cyanide, and one-half ounce of zinc cyanide to each gallon of water. All the tanks were theoretically operated at 85° F, voltage three, amperage fifty.

In general all of the chemicals and raw materials were those commonly used in copperplating, namely, copper sulphate, nickel sulphate, a potash cleaner known as "Clepo," sodium cyanide, sodium hydroxide, copper cyanide, zinc cyanide, Chipso, boric acid, sodium bisulphite, soda ash, sodium chloride, sulphuric, nitric and muriatic acids, ammonia, hydrogen peroxide, Oakite, and a grease solvent containing twenty-four per cent by weight of trichlorethylene.

It is important to note that all of the plating was confined to copper, bronze, and nickel. No chromium plating was

done and no chromium or chromium salts were used in this plant

Personnel

At the time of our study, there were seventeen regular full time employees in the plating department, in addition to which two other employees, a forelady and the electrician, frequented the plating room in the course of the day

gestion of the nasal mucosa with superficial sloughs of varying size on the anterior portion of the septal wall, middle and inferior turbinates. In a large percentage, ulcerations of considerable size and depth were present at these sites. Two of the employees developed septal perforations during the course of observation and treatment. In all cases, pharyngeal congestion was pronounced. The essential facts with reference to the eigh-

Fig 1

Of the seventeen regular employees, nine had been engaged in this particular work for a short period of time ranging from one to eight weeks. The remaining eight were veterans with several years experience. One of these had recently been promoted to the position of foreman. Neither the new nor the old workers gave a history of nasal disturbance prior to this episode, but now all were affected.

Medical Findings

The characteristic lesions uniformly found were an intense widespread con-

teen cases are summarized in Table I, and the nineteenth case, that of the departmental foreman is herein described in detail separately because his case came to autopsy.

The departmental foreman, age twenty-two, reported at the office two weeks after our investigation had been in progress. He had been engaged as a plater with the present employer for six months, the last two of which, he had been acting as the foreman. In his experience of eight years with plating operations, he had never suffered any nasal complaints.

His present complaints dated back two months and consisted of "alternate running and dryness of the nose, nasal bleeding

obstruction and headache—teeth all hurt” There was no conjunctival disturbance. No skin lesions. No cough or vomiting. His general health had been poor and he had lost weight. The acute symptoms developed two days prior to the examination and were severe pain and swelling of the nose. He had remained at work.

Examination General condition poor, appeared acutely ill, temperature 98.8, pulse ninety-eight. *External Nose*, Right ala swollen and very tender, circum-

ous sinus thrombosis, basilar meningitis, septic pleurisy, septic pneumonia, and septic infarct of the right lung

Past Record

In addition to the preceding personnel findings a survey of the past records of this employer was made. There was found one instance of identical complaints relating to a plater employed for one month who developed acute coryza, etc

TABLE I

Case	Duration plating exposure elsewhere	Duration present exposure	Duration of present complaints	Course and end result
1	None	Six weeks	Two weeks	Small anterior perforation
2	None	Three weeks	Three weeks	Large anterior perforation
3	None	One week	One week	Cleared up completely in several weeks
4	None	One year (Electrician)	Three weeks	Cleared up completely in several weeks

scribed tender swelling about three-quarters of an inch in diameter just to the right of the bridge. *Internal Nose*, On the lateral wall of the vestibule, on the right, there was a small carbuncle, partially ruptured and covered with a black crust. Septum and both middle and inferior turbinates covered with heavy crust and slough, underlying which, were ulcerations in spots. *Throat*, Congestion of the faucial pillars, uvula and posterior pharyngeal wall. Tonsils enlarged and inflamed. *Heart and lungs* Normal. X-ray of thorax was negative. Noticeable pallor of skin and conjunctiva.

Because of these findings and the possibility of grave complications, he was immediately admitted to the hospital. That night, temperature rose to 104, shortly after, the lesion spread to the right eyelid. His course was rapidly retrograde. He developed pneumonia of the left lower lobe and signs of meningeal irritation. Death ensued in five days.

Autopsy findings included ulceration of the septum, middle and inferior turbinates, carbunculosis of the tip of the nose, cavern-

The rhinologist reported an early erosion of the nasal septum. Exposure was discontinued and he was under treatment for seven weeks. A full recovery followed. No efforts were taken at that time to trace or eradicate the cause of the trouble.

Plant Conditions

The plant had been in operation under the present management for several years. It was claimed that the same chemicals and procedures had been in use unchanged during that time. About four months before, however, as a result of the objection from employees in the adjacent departments to the irritating odors, wooden separating partitions (described earlier) were erected.

On repeated visits to the premises, a strong odor of hydrocyanic acid, excessive moisture, and general bad house-keeping were apparent. These conditions prevailed to a greater degree late in the afternoon after the plant had been in

operation for several hours. In the plating room there were no provisions for artificial ventilation. The ventilation (natural) was dependent solely on the opening of the windows and the gaps in the wooden partitions. In the acid room over the acid crocks there was an exhaust hood and a small suction fan.

Study of the plating operation disclosed that as a result of changes in the process and the working conditions, there had been an increase in the amount of spray emanating from the cyanide baths. The alkaline mist thus produced contained sodium copper cyanide, free sodium cyanide, as well as caustic soda. The excessive spraying resulted from the operation of the cyanide baths of an abnormally low metal content at increased current and higher temperature. Continued study of the problem directly traced most of the atmospheric contamination to one bronze and four soft copper plating tanks. These were located farthest from the windows which served as the main source of ventilation and which in cold weather (February) were closed.

The mist or spray thus generated was inspired and produced by its local accumulative action, the lesions previously described. Where there was mouth breathing, the nasal passages were relatively free. The reaction occurred chiefly in the pharynx and larynx.

In brief, the direct causes of the disturbance were (1) Improper control of baths, (2) Failure to exhaust the spray thus produced, (3) Inadequate general ventilation, Bad general housekeeping was the contributing cause.

Subsequent reports of the chemical engineers were in accord with this general explanation and we are privileged to quote from their report as follows:

The partitions, built several months ago, restricted the natural ventilation, so that any unfavorable condition that may have existed prior to that time was accentuated. There was a strong smell of hydrocyanic acid and cyanogen gas which, although not a desirable condition, would not account for the lesions suffered by the workers. These lesions were traced to a spray arising

from the copperplating tanks, which menace would be corrected by installation of the necessary ventilating equipment. Further, it was found that the metal content in the brass tank and in two of the copper tanks was considerably below the amount customarily used. A low metal content causes an abnormal amount of spray. Contributing causes were improper housekeeping.

Suggestions were made as to proper floor drainage, use of additional floor boards which would serve to raise the heads of the workers a few inches more above the tanks and finally, steps to be taken to avoid undue heat and excessive current by the installation of an ammeter, a voltmeter, and a thermometer attached to each tank. The four things to be watched were the ventilation, the proper control of the solutions, the maintenance of the proper current and temperature in each tank, and general housekeeping.

As a result of our findings, the plating department was shut down for several weeks during which time the recommendations of the consulting engineers were carried out and then work was resumed under experienced supervision and proper control. The previously manifest disturbance was effectively corrected. There were no recurrences of the difficulties in the old workers, nor did any appear in new employees.

A review of the literature has failed to disclose any reports of ulceration of the nasal mucosa or septal perforation in the copperplating operations. Cases are mentioned in connection with copper smelting. These are attributed to the inhalation of dust and the deposition of arsenious oxide on the nasal mucosa. There is a record of one case of ulceration of the nasal septum of an employee engaged in dipping parts in solutions of nitric and sulphuric acids. The man, however, did not work at the cyanide tanks. Undoubtedly, lesions similar to those described have been overlooked in the past and constitute a definite industrial hazard readily controlled by frequent check-up of the process and working conditions by repeated examinations of those exposed.

favorite flower of the diabetics is the sweet pea

STERILITY AS A CLINICAL PROBLEM IN WOMEN

W T POMMERENKE, M D, *Rochester*

From the Department of Obstetrics and Gynecology, University of Rochester School of Medicine and Dentistry

Sterility should be regarded as a symptom rather than as a disease entity. In a strictly limited sense it denotes the inability of the woman to become pregnant. The term admits of various interpretations however. In ordinary usage it applies also to the woman, who, though she is able to conceive, is nevertheless unable to procreate. In this latter and broader sense, the fact that conception may occur is of little moment if, due to such accidents as abortion or ectopic nidation, the pregnancy does not progress to the period of viability of the child.

An absolute sterility is one in which conception fails to occur. This may result from congenital defects or major pathological conditions. The absence or extreme maldevelopment of the uterus, and the presence of large uterine or ovarian tumors fall within this category. In relative or apparent sterility the ability to conceive and procreate a living child is not impossible, but difficult or unlikely under existing circumstances. Here the egg does not get a proper chance to become fertilized. If pregnancy has never occurred, the condition is referred to as a primary sterility. Secondary or acquired sterility refers to the failure of pregnancy to occur following a previous abortion or delivery. Using the above general classification, we are not concerned with the physiologic infertility associated with the menopause, lactation, menstruation, and the period immediately preceding or following it, or with the application of the so-called "safe period" championed by Knaus,¹ Ogino,² and others. Furthermore, we should not charge a woman with sterility without allowing her sufficient opportunity and time for becoming pregnant. In this respect the time factor is variable, depending in part on the age of the woman. Generally speaking, a woman may be said to be presumably sterile if conception does not occur within three years of

life with a sexually normal partner, provided, of course, that no contraceptive measures have been used. Polak³ has stated that only about seven per cent of women bear children after the third year of married life. Presumably he referred to the first pregnancy.

Incidence

Obviously it is difficult to gain exact figures as to the incidence of sterility within a population. Popular impression is apt to attribute sterility to defects of the female, whereas we know for a fact that the male should share the responsibility in a considerable percentage of cases. Many cases never come to medical attention since couples frequently will bear their lot silently and hope that nature will in time somehow remedy the situation. Various estimates (Polak,³ Crossen,⁴ Green-Armytage,⁵ and Meaker⁶) place the incidence of childless marriages at about ten per cent. In England, according to Green-Armytage, fifteen per cent of pregnancies end in miscarriage, and Meaker estimates that there must be some 2,000,000 childless couples of the child bearing age in the United States alone.

Several conditions are essential for a successful pregnancy, viz

- 1 Healthy active spermatozoa in sufficient numbers must be deposited to gain access into the cervical canal without being stopped in transit or inhibited by inimical secretions.

- 2 The ovary must yield normal mature ova.

- 3 The uterotubal tract must permit outward migration of the sperm and the inward transit of the fertilized egg.

- 4 A healthy and properly prepared endometrium must be in readiness for the nidation of the ovum.

Any defect in the above requirements may prevent impregnation. Frequently however the summation of multiplex

sub-threshold factors is responsible for sterility, and for this reason it may be a difficult task to assign the reason to any specific fault as it applies individually to either husband or wife. Reynolds and Macomber⁷ have suggested that apparently normal persons vary greatly in relative fertility. Thus a person of low fertility may succeed in reproducing when mated with one of high fertility, but may fail when mated with a person of lesser reproductive aptitude. In other words, the fertility of any given mating is the summation or product of the fertility of the two individuals concerned. These same workers observed that dietary deficiencies in fat soluble vitamins, protein, and calcium though they be too slight to produce ill health, in the animals studied, are nevertheless associated with a definite decrease in fertility.

Faulty diet, mental strain, and physical inactivity have been cited by Meaker⁸ as logical causes of depressed constitutional states resulting in sterility. It would be difficult to enumerate the whole list of similar contributing factors. These comprise a long list of local and general debilitating diseases, notably marked anemia, obesity, and tuberculosis. Syphilis has long been credited with being a major cause of infertility. Though the disease apparently does not hinder fertilization, it nevertheless frequently causes abortion. Subsequent pregnancies may be carried longer, and finally to term. If no disease is found, it is often assumed that the sterility is due to some functional disturbances. But to let the matter rest here, is to admit lack of inquisitiveness in the search for a more manifest cause. However, it would appear that psychosexual incompatibility along with frigidity and vagismus are obscure though real impediments to fertilization. A classical example of selective sterility is illustrated by the story of Napoleon and Josephine. Each was able to demonstrate fertility with another mate, but together they were fruitless. Although it is generally agreed that an orgasm in woman is no requisite to fertilization, strong sexual feeling probably increases the likelihood of impregnation, according to Crossen.

That industrial disease may play an important role in the etiology of sterility, is suggested by Irving⁹ who states that plumbism by influencing either the egg or the sperm may reduce fertility. Chronic morphinism and alcoholism have likewise been adjudged guilty in this respect.

The husband should not be absolved of guilt for a sterile mating without definite evidence of potency. Polak has estimated that about thirty per cent of the fruitless marriages are due to sterility of the male, while Naeggerath¹⁰ claimed that ninety per cent of sterile women are married to men who at one time have had gonorrhea. A zoospermia was found in over thirty-three per cent of 206 sterile marriages by Kehrer and Sanger.¹¹ Other observers^{5, 6, 12} likewise have placed the incidence of male responsibility in sterile marriages at twenty to fifty per cent.

The prominence of gonorrhea as the etiological agent in the causation of sterility is illustrated by the estimate of Polak that fifty per cent of these cases are due to the gonococcus. This organism may produce an orchitis which inactivates the sperm, or, by causing an epididymitis, may lead to blockage of the ducts. Cryptorchidism results in failure of the testes to develop. The testis may be rendered useless from a reproductive standpoint by such specific diseases as tuberculosis and syphilis. Atrophy of the testes may result from parotitis, alcoholism, drug addiction, or from chronic debilitating disease. Sexual exhaustion from excesses may produce an oligospermia with resultant marked diminution in the number of cells. Irving cites 100,000,000 spermatozoa per cc as a normal count. Although pregnancy is possible with a lesser count, its likelihood increases with a greater number of sperm.

Even though normal sperm cells are found, the male may still be at fault because of a hypospadias or premature ejaculations. Recourse is made to the microscope for determining the adequacy of the semen. One should note the number and activity of the spermatozoa. Deformities, particularly of the head, should

STERILITY IN WOMEN

Number 111

be sought. If faults in the production or delivery of the spermatozoa are found, the man should be placed in the hands of a competent urologist.

The ovaries and other endocrine glands have a direct bearing on sterility. Green-Armytage found that forty-four per cent of his cases were due to genital hypoplasia. Anovular menstruation was found in some fifty-five per cent of the sterile women studied by Mazer and Ziserman,¹³ and in about twenty-one per cent of the cases reported¹⁴ that had complained of obesity and sterility despite the fact that they had regular uterine hemorrhages. Novak¹⁵ has also emphasized anovular menstruation as a cause of sterility. Bland and coworkers¹⁷ observed that primary deficiency of the anterior lobe of the pituitary gland is a noteworthy form of endocrine disturbance in sterile patients.

A diminished amount of female sex hormone in a considerable number of patients with sterility has been demonstrated by Frank.¹⁶ Marked displacement of the ovaries often diminishes the chances of pregnancy by making migration of the egg into the tube difficult or impossible. Fibrous adhesions following pelvic inflammation frequently bind down the ovaries so completely that escape of the ova is quite impossible. The fibrosing influence of radiation therapy is familiar. The intimate functional relationship between the pituitary and thyroid glands to the ovaries is generally recognized, and any significant derangement in these glands may become an important factor in the causation of sterility.

Developmental errors are prominent causes of sterility of the female. Among these may be included the partial or total absence of organs, malformations of the vaginal, cervical, or tubal orifices, underdevelopment or malposition of the uterus or ovaries. These serve as mechanical barriers to fertilization, and their discovery easily establishes the etiology of sterility. An atretic or resistant hymen, or a stenosed vagina, along with pain, may render the sex act impossible, painful, or incomplete. Postoperative cicatrices may likewise seriously inter-

fere with intercourse. Improper drainage of the vagina may be conducive to bacterial and chemical changes which result in spermocidal effects. A shallow vaginal vault or marked relaxation of the vaginal walls and perineum may cause effusion of the semen. The normal pH of the vaginal secretion is about four. According to Green-Armytage this is not particularly harmful unless an excessive amount is present in which event the sperm cells may be attenuated or killed within fifteen minutes or before they can reach the cervix, which like semen has an alkaline secretion with a pH of eight to nine.

That spermatotoxins may contribute to sterility is suggested by experiments on animals. Dittler¹⁸ found that female rabbits could be made sterile by the intravenous injection of fresh ejaculation fluid of the male rabbit. McCartney¹⁹ observed a similar phenomenon with rats. Kohlbrugge²⁰ stated that there may be a penetration through the genital epithelium and an invasion into the underlying connective tissue of the female rat and other rodents by spermatozoa after normal coitus. Waldstein and Ekler²¹ were able to demonstrate postcopulatory ferments which were not present prior to copulation and which led to the absorption of sperm. Mayer²² believed that sexual intemperance in women may lead to premature rupture of the follicles and thus cause sterility. He further stated that pregnancy frequently resulted after periods of sexual abstinence during the Great War, when the soldier husbands had infrequent leave from the front, the prolonged abstinence apparently remedying the sterility due to overloading of the genital tract with sperm. Vogt²³ likewise raised the question if sterility in women might not be the result of sexual excesses. It was his observation that often couples, whose matings had previously been sterile, become fruitful after periods of separation or abstinence.

Stenosis or atresia of the cervix is a readily understandable factor in the etiology of sterility. Hypertrophy of this organ, along with the mis-direction of its axis away from the receptaculum are

possible impediments to cervical insemination. In the experience of Wharton forty to fifty per cent of sterile women had a pathological cervical discharge. A tenacious mucous plug in the cervix not only serves as a mechanical barrier which makes sperm penetration difficult but the pus in which the cervix is bathed is actually lethal to the spermatozoa, according to Rubin.

The uterus itself may be the cause of sterility. An infantile uterus may be only a contributing factor, general genital hypoplasia representing the underlying pathology. The presence of a chronic infection of the endometrium may be the basic factor in sterility. The use of the stem pessary as a contraceptive device probably owes its efficacy to setting up a chronic endometritis which prevents proper nidation. An infected polyp may act in much the same manner. Fibroids are not at all necessarily incompatible with pregnancy. Their presence may however favor an abortion, their effects being largely proportional to their size and position.

Tubal disease is without doubt one of the most prevalent causes of sterility. Irving estimated that it is responsible for about twenty per cent of the cause of sterility in women. Occlusion of the tubes was responsible for 39.8 per cent of 2,000 sterile marriages that came under the personal observation of Rubin,²⁴ and Green-Armytage placed the incidence of this condition at about fourteen per cent. These computations appear quite representative. While endometriosis, tubal spasm, diverticulation, angulation, along with developmental errors of the tubes, contribute a fair proportion of cases of tubal occlusion, inflammatory causes predominate. Important in this respect are the infections resulting from abortions and septic puerperal states. Appendicitis may also lead to tubal occlusion by sealing the fimbriae. Tuberculosis may also be the etiological factor. Ranking about on a numerical par with postabortal infection, gonorrhea is a major cause of tubal sterility, and because of this fact gonorrhea has not only individual but also far-reaching racial significance.

Routine Procedures

Success in the understanding and treatment of sterility depends directly on painstaking and detailed attention to many contributing factors. Search should be made for as many possible causes as can be found or suggested. Cessation of the search after the discovery of one or two apparent etiological factors may lead to therapeutic failure. Correction of several or many sub-threshold influences will frequently be required to raise the fertility to a state where procreation is possible. Intelligent investigation calls for a detailed inquiry into the medical history as well as into the physical and psychosexual status of the patient. Discovery of the cause will suggest the procedure to be followed. Inquiry into the family history should reveal if the patient comes from prolific stock. The patient should be questioned about any serious childhood or adolescent disease which may have produced lasting and debilitating effects. The menstrual history should tell much considering the gonadal development. Special note should be made of the late puberty and of scant and painful menstruation. Significant weight changes may hint of endocrine disturbances. Acquired dysmenorrhea may suggest endometriosis. A story of lower abdominal pain or appendicitis may cause one to suspect tubal involvement. One should inquire concerning the type of contraceptives used and the duration of their use. Attempts should be made to determine the history of venereal disease by symptoms and by name. One should learn of the existence of any coital difficulties and of the psychophysical response. The husband may be able to furnish supplementary information on these latter points. In other respects too he must not be left out of the reckoning. The history of an induced abortion, particularly if followed by infection, may provide the all-important clue to the troubles at hand.

A complete general physical examination should follow the history. Any unusual bony development, girdle obesity along with abnormal quantity, distribution, and texture of hair may suggest a faulty endocrine endowment. Special

emphasis should be placed on the findings at pelvic examination. Anomalies of the vulva and hymen should be noted. Possible explanations for dyspareunia or nonpenetration may thus be readily ascertained. Any hypertrophy or atrophy of the labia minora or clitoris should be observed. In the vaginal examination an abnormal or excessive secretion should be studied and tested for relative acidity. Physical reasons for effusion of semen should be sought. The position and axis of the cervix should be ascertained and the accessibility of the external os to the seminal pool determined. Any lacerations or evidence of chronic infection should likewise be noted. The patency of the cervical canal and the character, and particularly the reaction and tenacity of the mucus should be determined. The uterus should be studied and examined for size, position, symmetry, and movability. Attention should also be given any thickening, swelling, fixation, or tenderness of the appendages. One should of course take notice of the presence of any pelvic tumors. The endometrium can be studied for evidence of ovulation by removing scrapings with a small curette. This can be done as an office procedure preferably just prior to an expected menstrual period. Study of the woman is not complete without blood counts, a Wasserman test, and examination of the urine. It may be necessary to perform general metabolism tests and to determine the level of various hormones by methods which Frank and others have described.

No major diagnostic or therapeutic procedure for sterility for the female should be begun without first excluding the husband as a causative factor. A condom specimen of semen will give information concerning the number, mobility, and morphology of the spermatozoa. The patient is instructed to wash the condom in clear tap water and dry it before use. After coitus, the sac is tied to prevent leakage and returned to the vagina where the contents may remain at body temperature until the patient returns for examination. This method, however, does not tell how the

spermatozoa will be effected by other local conditions within the vagina. To get more accurate information on this point, the procedures recommended by Huner²⁵ should be applied. The patient is examined at intervals shortly after normal coitus. It should not be necessary to state that the use of any lubricant is prohibited. The vaginal, cervical, and fundal secretions are studied microscopically to determine the presence, number, and condition of the sperm *in situ*. If healthy spermatozoa in ample numbers are found within the cervical canal two hours after coitus, the husband can probably be absolved of his part in a sterile mating.

Earlier a laparotomy was required to determine the patency or occlusion of the tubes in a case of suspected sterility. Rubin has devised a method, now in widespread use, to determine the patency of the tubes by gas pressure. It is possible to pass CO₂ or O₂ through the uterus and into the peritoneal cavity provided one or both tubes are open. In general about 100-150 cc of the gas under a pressure of 100 mm of mercury will suffice to produce a pneumoperitoneum, evidenced by a fall in pressure, by fluoroscopy, or an x-ray film. Subjectively the presence of a subphrenic pneumoperitoneum is generally denoted by shoulder or interscapular pain. With a stethoscope applied to the lower abdominal wall one may hear a characteristic gurgling sound as the gas escapes into the peritoneal cavity. If the tubes are occluded, the pressure should not be allowed to rise above 200 mm. A temporary spastic condition at the tubouterine junction may give a false negative test, but can generally be overcome by a preliminary injection of atropine. If three or four failures to pass the gas into the peritoneum in tests spaced at intervals of about one month are observed, one is probably safe in concluding that the tubes are blocked. It has been observed frequently that under the influence of gas pressure the fimbrial adhesions which caused the occlusions are lysed with re-establishment of patency of the tubes. The test thus has therapeutic as well as diagnostic value.

The introduction of the cannula into the cervix may have an additional beneficial action. For theoretical reasons the test should probably be performed a few days before the expected time of ovulation. The test should not be performed during the acute stage of a pelvic infection. Neither should it be applied during menstruation or immediately following a curettage lest endometrial fragments be driven into the tubes or peritoneal cavity. Some workers prefer to substitute for gas, a fluid medium which is opaque to x-rays. Iodized oils have been employed for this purpose. Objection to their use has been raised because of their failure to pass by a tubal spasm and because they may cause a local inflammatory reaction due to slow absorption. A good x-ray film, when such oil is used, may be of great value however in telling of the nature and position of an obstruction, thus facilitating any subsequent surgical procedure.

The method of sterility becomes quite obvious when the cause is discovered. The cause or causes however may be elusive. Every case must be individualized. All mechanical impediments to fertilization must be overcome. The correction of other contributing factors will include improved hygiene, and should lead to what stock-breeders are prone to call "good breeding conditions," meaning good physical condition. This takes into account adequate rest, exercise, and diet, and calls for correction of faulty modes of living. Evans and Burr²⁶ have stressed the importance of the anti-sterility vitamin E in animal experiments. The application of his findings to the human species may prove beneficial in some cases. The woman should keep an accurate menstrual calendar. This will aid in determining the time when conception is most likely to occur. In a large percentage of cases, ovulation occurs about eleven to sixteen days before an expected menstrual period. Efforts at fertilization should be concentrated during this period. Artificial lubricants may possess unsuspected spermicidal qualities and should be interdicted. The suggestion that the female may be sensitized by the sperm may be

followed by the recommendation of a restful marital holiday. If no physical basis of sterility is found, no major therapeutic procedure should be instituted until some three years after marriage except perhaps when the woman is over thirty years in which event the interval may be shortened.

Such an obvious minor local cause as an unruptured hymen can readily be treated by incision. An excessive acidity of the vagina may be corrected by a mild sodium bicarbonate douche, using a teaspoonful to a quart of warm water. This helps to dissolve the mucus from the cervix as well as to furnish an alkaline reaction. Systematic tamponing may be tried if the fornix is unusually shallow. On the other hand, if extreme relaxation of the posterior vaginal wall and perineum leads to the effusion of semen, an appropriate surgical repair is indicated. In the absence of an operation, the placement of a pillow beneath the hips has often been beneficial. If the cervix points away from the seminal pool, discission or partial amputation may be effective in furthering the likelihood of impregnation. Any cervical infection or severe laceration should be remedied. The use of a suitable pessary to correct retrodisplacement of the body of the uterus will also serve to direct the cervix backwards.

The finding of a stenosed cervix calls for ample dilatation. A curettage should be performed as a diagnostic procedure. This procedure should be done, when possible, during the premenstrual phase when one should be able to tell if ovulation has occurred. The curettage may in addition have definite therapeutic value by removing polyp or infected endometrium. Obvious tumors should be removed. When the curettage is done in conjunction with the Rubin's test, it should follow rather than precede the insufflation test. For chronic pelvic inflammatory disease a prolonged course of hot douches, and properly gauged diathermy treatments have great beneficial and frequently curative value. In recent years the so-called "Elliott treatment" has become quite popular in many circles.

The operations of salpingosotomy and hysterosalpingostomy have been em-

ployed with varying degrees of success. Details for these and allied procedures are available in modern textbooks. In cases of bilateral hydrosalpinx and pyosalpinx and severe chronic salpingitis there is little hope from operative procedures as they relate to sterility. Plastic operations on the ovaries may also lead to subsequent pregnancy. One should however shy of creating unwarranted hope from any operative procedure.

The subject of artificial insemination, a method long familiar to the stock breeder, has recently been publicized in the popular magazines. But what may be expected of it in the human species has not been fully determined experimentally. This procedure should not be undertaken in any particular case without full knowledge of possible subsequent social and legal complications.

Endocrine therapy has likewise come into the foreground in recent years. Tests for the activity of various glands are becoming more accurate and this fact will help place this line of therapy on a more rational basis. What has already been accomplished along these lines of approach is as yet only suggestive. Litzenberg²⁷ has reported that a third of some twenty-two cases of sterile women with a depressed metabolic rate became pregnant subsequent to the administration of thyroid. The intricate relationship between thyroid, pituitary, and ovaries makes interpretation of results difficult. Frank, Bland, First, and

Goldstein, and many others have reported encouraging results from the administration of various endocrine preparations. Green-Armytage reports that the treatment of anovular menstruation has been followed by success in three out of seven cases of his own experience. These had been given four 1 m injections of 100,000,000 units of Estroform during the first two weeks of the cycle and three injections of Pregnyl (100 rat units) during the last ten days beginning on the seventeenth day. The benefits of hormone therapy have been definitely established in selected cases and further study along these lines is distinctly warranted.

Any discussion of sterilization would hardly be complete without mention of the need of prophylactic care in youth and adolescence directed at preventing the ravages of chronic and debilitating disease. The need of early and vigorous treatment, particularly of gonorrhea, cannot be overstressed.

Therapeutic procedure must frequently be experimental in nature. Husband and wife must agree to cooperate with a full and complete study which may require the services not only of the gynecologist but also the special talents of the internist, urologist, endocrinologist, and roentgenologist as well. Patient and painstaking attention to the correction of all contributing factors will be rewarded with the greatest probability of a successful conception.

INJURIES AND INFECTIONS

A Study of Cases Occurring on the W P A Projects of the Pelham Bay Area

HARRY LOWENS, M D , *Bronx*

In connection with the proposed institution for the third time in this city, of a panel of physicians for the treatment of the injured employees of the W P A , the Chief of the Safety Department at Washington recently showed me some figures dealing with the incidence of infection in the country in general and of New York City in particular. The figures were of a very startling nature: an incidence of eleven per cent of infections in July 1936 for New York City and a much lower figure for the country in general. In the course of a few months this incidence dropped to four per cent for the city, but even this was higher than the national average of 3.51 per cent. The figures available in the central medical office at New York City are in sharp contrast to the above, being approximately 2.5 per cent* of infections for 1936.

The area served by this office, which is located at Pelham Bay Park, is not less than ten miles square in extent. The number of men employed is between 4,000 and 5,000. Most of these men are at work in the open, constructing roads, pouring cement, and in filling and grading operations. A very large bathing beach is being constructed at Orchard Beach requiring the erection of a large sea wall, a boardwalk, roads and parking spaces, bath houses, and various other buildings as well as sewage disposal facilities.

A considerable proportion of the men are employed in four large shops located in a former "drill-hall" at Pelham Bay Park. These are a metal shop, sheet-metal shop, stone-casting shop, and a carpentry and furniture building shop. There is also a very large warehouse located near these shops. The approximate number of men employed in these

shops and warehouse is 1,000. This area, where about twenty projects are in operation, is almost entirely made up of park land and has, therefore, very poor transportation facilities.

Serious Accidents

In the course of the year two fatal accidents were recorded. One could hardly be considered as an accident due to occupation or labor performed. This case was that of a heavy and florid man, aged sixty-five, who was very active and constantly busy, although his superiors did not think that he was well because of his labored breathing. He was seen at a shack where he had been brought in from the field and was found in a moribund condition. He died in the ambulance on the way to the hospital. He evidently had a hypertension and the diagnosis antemortem was a cerebral hemorrhage.

The second case was that of a man run over by an automobile while filling the tank of his car with gasoline. The accident occurred at 3.25 P.M. on an isolated road, about 2½ miles from the medical office. Telephone facilities were not available in the immediate neighborhood, and very few W P A workers were in the vicinity of the accident. This man sustained a fracture of both legs, one of them compound with severe bleeding from the wound. It took the city ambulance forty-five minutes to reach this patient. The project physician was not informed of this accident until the following day. This patient had a transfusion following his admission to the hospital and the leg with the compound fracture was amputated. He died shortly after the operation, probably as a result of the severe hemorrhage which he had sustained. If the project physician had been notified promptly he could have reached the patient within a few minutes.

* A request for a copy of the Safety Department's tabulation was denied because the figures are supposed to be confidential.

and the bleeding would have been promptly controlled which might have affected the final outcome

There were no other serious accidents in the course of this year involving the loss of eyes, or amputation of either of the extremities, fingers or toes. There were a number of fractures, mostly of small bones of fingers, toes, and ribs. No definite skull fractures, proven by x-ray, were encountered. No fractures

of long bones are on record for the period. There was one case of fracture of the transverse processes of the lumbar vertebrae without cord injury. This unusual record I do not consider as merely fortuitous, my feeling being that both the safety inspector and the project physician were very conscientious and cooperated very effectively in the prevention of accidental injuries. Surely the fact that such a hazardous place as a lumber factory not having had one serious accident in the course of a year speaks volumes for the effectiveness and possibilities of preventive safety devices and proper supervision of the men at work.

The cases treated by the project physician at Pelham Bay Park during the year 1936 are clearly shown on Chart I, a tabulation of the total injuries numbering 3324. There is also shown on the same chart the number of subsequent treatments, which were 1672, a ratio of about fifty per cent for the year. The curve for the total injuries shows one particularly sharp rise with the peak reached in June. This occurrence can be readily explained by the fact that at this time the work at Orchard Beach, the largest project of this area, was being accelerated for the purpose of opening

a section of this project for the use of the general public of this city. Not only was the construction rushed, but the number of men employed here at the time was markedly increased. The rise and decline of the other peaks in this graph can be explained by seasonal variations and also with reference to the total number of men employed on the projects of this area.

The noninjury or medical cases totaled 1050 during a period of about ten months. These cases were made up in part of physical examinations given to employees where they had reason to believe that physical disabilities prevented them from doing certain types of work. They were either discharged and put back on relief as unemployable or given work better suited to their physical status. The majority of cases, however, were made up of acute illnesses, such as colds, abdominal disturbances, colics, both renal and gall-bladder, cardiac cases, fainting spells, epileptic fits, etc. All of these cases were treated once only and properly disposed of—no subsequent treatments in such cases were given.

The sharp drop in the number of medical cases in October, November, and December was due to an order, issued on October 21, 1936, by the New York City W P A Administrator, prohibiting the medical men in the field from attending any kind of acute medical case. This order was vigorously protested by the Medical Department without any result. Needless to say, such an order definitely endangered the health and well-being of over 200,000 men employed in this city and surely contributed to the spread of the epidemic of influenza.

Referring to the matter of costs and the relative value of the services rendered by the Medical Section of the W P A, it may be interesting to note the following data for the year 1936:

3324 cases—First treatment at \$3.00 (prevailing rate in New York City)	\$ 9,972 00
1672 cases—Subsequent treatment at \$2.00	3 344 00
1050 cases—Medical, at \$2.00	2,100 00
Total	<hr/> \$15,416 00

The yearly rate of pay for a project physician was \$2100 until December

1936. In December the pay was raised to \$2400 per year.

Under the panel system the cost of medical service will of necessity be greatly increased by reason of the greater proportion of subsequent treatments, which under the present method is but fifty per cent of the total number of injuries. Likewise, because of the delay in rendering medical care to the injured, the number of infections will be materially increased, and this will, of course, add to the cost of medical care. And finally, the time lost in going to and from the panel physician may in the end cost more to the Federal government than the entire cost of medical care. A detailed study of this last item cannot be made, but this assertion is not at all unreasonable.

The number of subsequent treatments is clearly shown on Chart II. It is interesting to note that at the time of the peak of the injuries in June 1936, the number of re-treatments was comparatively low, that is thirty-two per cent. This was probably due to the type of injury, to the seasonal variation, and relatively lower incidence of infection. Only in November was the number of subsequent treatments higher than the total number of injuries, the percentage being 104. The total number of subsequent treatments for the entire year is fifty per cent of the total number of injuries.

Charts III, III-A present a division of the total number of injuries into two distinct groups: (1) comprising cases of abrasions and lacerations, (2) injuries with no actual break in the skin. This distinction is important with reference to the tabulation of infections occurring which are practically limited to the cases where the skin was broken. They also show a relationship of infections to both the total number of cases and to those showing a break in the skin.

Infections

The total number of infections for the year were forty-eight. The total number of injuries were 3324, of which 1868 had either a laceration or an abrasion of the skin. The percentage of infection to the total number of injuries is, therefore,

1 45 per cent, or, if based only on the number of cases having had lacerations or abrasions, 2 58 per cent (Charts III and III-A)

These charts likewise show the seasonal variation in the incidence of infection, although the occurrence of infection would presumably be highest during the hot season because of the maceration of the skin due to perspiration. This is not the case, however. The months of May and June with the highest number of injuries show a very low rate of infection, May showing 0 51 per cent for the total, and 0 85 per cent for lacerations and abrasions, and June, 0 68 and 1 29 per cent respectively. The highest incidence of infection was in the months of October, 2 32 and 4 72 per cent, December, 3 53 and 5 83 per cent, January 2 46 and 4 87 per cent for ratios to total number of infections and lacerations and abrasions respectively.

Considering the limited total number of infections—forty-eight for the entire

year—no generalized conclusions can be drawn from the data presented.

As a measure of the severity of cases reported, the number of treatments rendered to each of the patients who was diagnosed as having an infection

23	patients received	1	treatment
10	"	"	2 treatments
7	"	"	3 "
2	"	"	4 "
4	"	"	5 "
1	"	"	6 "
1	"	"	7 "

Only one case was sent to the United States Marine Hospital for treatment, and this was the only case for the entire year in which an infection resulting from an injury caused lost time and the payment of compensation. This patient allegedly sustained his injury on January 13, 1936, and presented himself at the medical office for the first time on January 20 with an infection of the palmar surface of his left hand. He was sent to the hospital on the same day.

Three cases out of forty-eight were referred to the central medical office, either because the cases were of a type which could be better served by a more properly equipped office and where medical assistance was available, or because of the doubtfulness of the injury being sustained in the course of occupation on a W P A Project.

The author tried to determine the period which elapsed between the injury

CHART III-A—ROTATION OF INFECTIONS TO TOTAL NUMBER OF CASES

LEGEND (d) Number of infections 48
(e) % of lacerations and abrasions 2 58
(f) % of total cases 1 45

CHART IV—NUMBER OF DAYS ELAPSING AFTER INJURIES BEFORE INFECTION SEEN BY MEDICAL OFFICER (OVER 2 YRS)

and the time when the patient sought medical care. This is shown on Chart IV. Twenty-eight cases out of a total of forty-eight, or fifty-eight per cent saw the medical officer within three days following the injury. One case of infection with a foreign body came for treatment more than two years after the original injury was sustained.

All of the forty-eight cases had their infections diagnosed when they presented themselves for their first treatment. In going over these cases of infection carefully I found that eleven had a very doubtful connection with the work which they performed for the WPA. These cases were as follows:

Hangnail infections	3
Infected hair follicle	1
Insect bites	2
Seen day of supposed injury with well-developed infection	1
Infection of toes and foot due either to paring of corn or ring worm, present on both feet	
Injury of supposed contusion of very doubtful origin	1
Infection of left shin—injured several times while at home and on job. Last injury at home a few days prior to first visit to doctor's office	1
Case seen first time fourteen days after alleged injury—infection of right thumb	1
Infection of right thumb—refused compensation by Federal Compensation Department	1
Total	11

Infections in cases of punctured wounds totaled five, all of which appeared in locations other than feet. The parts where the punctured wounds were infected were confined to the hands and fingers.

No infections were present in seventy-eight cases of punctured wounds of the feet in the course of the entire year. This record is probably unique. Dr. John J. Moorhead speaking on the subject of punctured wounds at the New York Academy of Medicine during the 1936 Graduate Fortnight expressed as his opinion that the only safe treatment for punctured wounds is to convert them into open ones. Had I followed this advice I would have had a great many more "loss of time" cases and very probably a great many more infections. The treatment of punctured wounds of the feet by the author was very simple indeed. The foot about the puncture was generally

CHART V—PUNCTURED WOUNDS

LEGEND (g) Total 156 cases
(h) Feet 78 cases
(i) Other parts 78 cases

cleansed with benzine and a probe dipped in a 3½ per cent iodine solution was introduced either once or twice into the tract of the wound. A simple dressing of gauze and adhesive tape was applied. Very few subsequent treatments were necessary and no one lost any time because of such injury. In cases where a patient with such a wound returned for further care, the same treatment was repeated.

Referring to Chart V, punctured wounds of the feet, the peak of the curve corresponds to the peak in Chart I and its cause is the same in both cases, that is, the attempt to complete a section of the Orchard Beach project in time for its use by the general public.

A study of the punctured wounds of

CHART VI—EYE INJURIES

LEGEND (j) Total 92 cases

(l) Elsewhere 102 cases

the feet was made with a view to possible prevention, and the matter was brought to the attention of the Safety Inspector of my location. Subsequently a great many punctures were prevented because of the organization of a crew of men whose duty it was to remove boards with nails as soon as they were discarded. This crew operated at Orchard Beach where the greatest part of these injuries occurred.

CHART VII—EYE INJURIES W P A IRON SHOP
—1936 (PELHAM BAY SECTION) TOTAL
No OF CASES—90

Needless to say that tetanus antitoxin was used in practically all of the punctured wounds of the feet, and no case of tetanus occurred during the year which this report covers.

The last part of this study deals with eye injuries (Charts VI and VII).

This study was likewise undertaken for the purpose of reducing the number of eye injuries. I have divided the total number of these injuries, all of which were in the nature of foreign bodies, into a preventible group which occurred in the iron shop and those in the field.

The injuries in the iron shop occurred in the process of grinding metal and were caused either by a metal particle or a particle of emery from the grinding wheel. The injuries occurring in the field were not subject to prevention because they consisted of foreign bodies blown into the eyes by the wind. The number of cases in the iron shop was

a total of ninety for the entire year. In following the curve on Chart VI, the drop in the incidence in the number of eye cases in the iron shop in March can be attributed to the introduction of goggles for the protection of men who were employed in grinding operations. The curve, however, gradually rises, probably because of inadequate supervision and negligence, but it never reaches the peak of February. The second peak is in August, when the curve again begins to descend, reaching an all year low in October.

Chart VII shows the distribution of eye injuries among the men employed in the iron shop. It is worth noting that two men accounted for twelve per cent of all eye injuries, one having had six individual injuries and the other five. It is evident that these two men should not have been permitted to do any metal grinding whatsoever. Furthermore, three men sustained three injuries each. These men likewise should be watched carefully to determine their fitness for grinding operations. Eight more men had two injuries each and these men should be kept under proper supervision while working at the emery wheels.

One factor omitted from this report which should have been included is a monthly average of the number of men at work on each of the projects covered. The writer tried to obtain this information, but it was denied to him. Another item which the writer unsuccessfully tried to obtain for checking purposes was the number of "loss of time" cases.

To summarize, this study shows (1) the low cost of treating the W P A injured, (2) the small ratio of subsequent treatments to the total number of injuries, (3) the low rate of infections, which in the last analysis is surely due to the promptness with which the injured were cared for, (4) the demonstration of the possibility of escaping infection in such dangerous injuries as punctured wounds of the feet and the possibility of preventing such injuries, (5) the care and prevention of injuries to the eyes in such dangerous occupations as the grinding of metal and the elimination of the men who are careless and grossly negligent in the operations of grinding.

COMMENTS BY A COUNTRY DOCTOR

Time—1893–1933

B P ALLEN, M D, *Oriskany*

I might compare this paper with the dictionary. A man was reading a dictionary, when his friend asked him how he liked it. He replied, "Well, it is a very interesting story, but I find it slightly disconnected."

I am sure this paper is "slightly disconnected," and can only hope you will find it interesting.

In this short contribution, I wish to comment on some of the many changes that have taken place in the last forty years, especially those changes that have affected the practice of medicine.

First, let us consider transportation. While some physicians used a bicycle about town and for short outside calls the horse-drawn vehicle was the principal mode of transportation used by physicians in both city and country. Now it is the automobile. The change from horse to automobile was slow at first, especially in the country, but became rapid as soon as more reliable automobiles were made and good roads began to appear. All things considered, the horse was pretty satisfactory and I think many country physicians were sorry to make the change. One thing I know—when I gave up horses, I also gave up my only hobby.

Many country physicians thought the automobile would greatly increase practice, for they reasoned, with good roads and more rapid transit they could take on more patients at a distance. This may have proven to be the case in some instances, but not in all, and for the following reasons.

It is true that with the auto the doctor could make his calls more rapidly and easily but it is equally true that very soon the farmers and out of town patients also had machines and could and did more often consult the doctor in his office than formerly. And unfortunately for the small town man, all of his former patients do not stop to see their family physician but drive right by and consult city physicians instead. Perhaps they are like the man who said he always employed a doctor who had his office on Genesee Street, because if he

did not he was not much of a doctor anyhow. Now this may be true—but I doubt it.

In 1893, when I began my practice in Oriskany, we had so-called roads, where we now have state, county, and town highways. No country roads were hard surfaced and in the Spring and late Fall we waded through mud, in the Summer, if it happened to be a dry season we were smothered with dust and in the Winter we struggled through storms, snow banks, and pitch-holes. The roads were not kept open in Winter as now and when after a bad storm an attempt was made by the farmers to open them, they always followed the direction of least resistance with the result that the Winter roads were through the fields instead of between road fences. All too often the doctor in going to his patients broke his own road and if this proved impossible he was supposed and often did tie his faithful steed to a tree or fence post and continued his journey on foot.

In the village there were no sidewalks worth mentioning, no sewer system or city water. Water supply was from wells often infected or impure and only outside toilets or privies were used. Houses were lighted by oil lamps and the village streets by an occasional lamp or lantern, if at all.

When the doctor was called at night he either carried a lantern or walked in the dark and many is the time I have said, "Oh, please excuse me," when I have bumped into a tree thinking it a fellow pedestrian. We also had no telephones or street cars. Later, of course, we had both and now telephones are numerous even in the country districts.

Many of the diseases we treated forty years ago are seldom encountered now. Typhoid fever was one of these. Beginning in September or early October every year, we had many cases, but since we substituted city water for wells and constructed a modern sewer system to take the place of outside toilets, the disease has practically disappeared. My last case was in 1913.

Typhoid was a mighty severe disease, one that usually kept a patient in bed for six or eight weeks and was always followed by a slow convalescence. Mortality was not too bad considering, but there were many deaths.

Summer diarrhea in children and in older people kept us busy especially in July, August, and September. Nearly every child under five years suffered from this disease during the season and the death rate was very high.

The present infrequency of diarrheal diseases I think can be accounted for by our sanitary milk and water supply and by the fact that, with the houses so well screened, we get away from the menace of the housefly. I might add also, that in my opinion, the average mother is much better educated and more efficient in the care and feeding of her children.

Diphtheria was one of the most dreaded of diseases and certainly took its toll especially of children under five years of age. Antitoxin was being used to some extent, but owing to the fact that it was very expensive—that the general public was afraid of it, thinking that it always depressed the heart and caused paralysis, we were unable to use it in many cases where we knew it to be indicated. Also, I fear we doctors used too small doses and not early enough in the course of the disease. Now, thanks to T A and toxoid we have, I think, this dread disease practically whipped. There have been no cases in my territory since 1925 and with so many schools and the pre-school children immunized, I certainly do not expect any epidemic of this disease.

One other disease I will mention, namely pulmonary tuberculosis. I think it is safe to say that an early diagnosis of this dread disease was seldom made forty years ago. When cases were diagnosed, they were often moderately advanced or very advanced and treatment did little or no good.

Now, with the great advances that have been made in the segregation, care, treatment, and early diagnosis of this disease, cases are no longer looked upon as hopeless. In fact, recent figures show the yearly death rate has dropped from one hundred and fifty to about fifty per 100,000 population.

All the credit however, does not go to the medical profession, for insurance companies and lay organizations have done

much to bring about these results. Preventive medicine was unheard of and certainly was not practiced to any extent, forty years ago.

Each town was supposed to have a health officer, but his duties were very light as compared with now. Many years ago I was appointed Health Officer of the Town of Marcy and felt very proud of it and, naturally, expected it would add considerably to my income. I soon found out my mistake for the Chairman of the Town Board informed me the appointment was only made to comply with the State law and I was supposed to do exactly nothing. However, if I had to investigate a nuisance I would receive two dollars for each investigation in the town. As my first year's fees amounted to just six dollars, I resigned. Compare that with conditions at present, a most efficient State Department, District Sanitary Officers, a Sanitary Code that regulates everything, wonderful County Hospitals to care for our tubercular and indigent patients, County Health Nurses, School Nurses, School Examinations, and Clinics too numerous to mention.

It would take too long even to mention all the changes that have been brought about by preventive medicine in recent years.

I cannot, however, refrain from making a few remarks on the management of milk. Forty years ago, the milk industry was under no supervision and anyone who had milk to sell could do so. No cows were tuberculin tested, no dairies scored, no milk pasteurized, cooled or bottled. All milk peddled was dipped from a can into pails or other receptacles left on the door step.

It seems to me we had more maternity cases back in the gay nineties than now. I really think I would have starved to death during the first eighteen months of practice except for the forty confinements I attended. I nearly did anyhow.

Why women will send for a young inexperienced doctor to attend them in maternity, has always been a mystery to me, but it is a lucky thing for the young man starting in country practice.

I believe I encountered nearly all the complications it is possible to have during my first year. I remember breech, foot, shoulder, occiput, posterior presentations, a case of hydrocephalus, and a monstrosity, to say nothing of about five pair of twins.

Practically all maternity cases were cared for in their homes. It was a rare exception that went to the hospital.

A great majority of our maternity cases had no prenatal care and often the doctor was not called "till the patient was in labor." The experience we older country doctors had in maternity cases would be most interesting, but my time is limited and I will not bore you with mine.

We certainly had some hard problems to solve and under very trying conditions. For instance, I was called to a case at one A.M. and had no previous knowledge of the patient, only candles for light, no clean towels or dishes, no trained nurse or other good help. Patient examined, dead baby, probably hydrocephalus, not a chance of getting another doctor to help. What would you do under the circumstances? One thing is sure—such cases did teach the doctor self-confidence and independence. And yet, notwithstanding the many disadvantages under which we worked, I think our maternal death rate compared favorably with the results obtained today, with all our prenatal care, improved technic, and hospitalization of patients.

I know of one country doctor who had only two maternal deaths in one thousand confinements. One was due to ruptured uterus in an otherwise normal case and the other to a postpartum infection, caused by the carelessness of an untrained nurse who was suffering from a badly infected finger at the time.

Without a doubt, the attitude of the people has changed much insofar as the so-called family doctor is concerned. Years ago the family doctor was consulted in every case of ill health. No matter if the case rightly belonged to the surgeon or the specialist his opinion was sought. Now quite often the first the doctor knows of the case is, that Mrs. Jones is in the hospital for an operation.

Speaking of hospitals reminds me of the changed attitude of the general public towards those institutions. Forty years ago the public thought of hospitals with dread and as a place to fight against. To send a patient to the hospital was usually a he-man's job, for the doctor had not only to combat the prejudice of the patient, but many times of the whole family as well. Now that feeling seems to be entirely absent, and, indeed, I think, at least some

patients go to the hospital who could be equally well-treated at home.

Just to mention again a few of the helps and conveniences we now enjoy, that we did not have forty years ago. We have good roads, automobiles, motorcycles, and airplanes. We have electric lights, electric refrigerators, and many other electrical things in our residences and in our offices.

We have telephones in nearly every home and all business places. We have vaccines and antitoxins for both prevention and treatment. We have radium, the x-ray, and the radio. And, what an educator is radio, in fact, whatever would we do without this most modern achievement of science, for without it how could anyone, or better, everyone have learned the great virtue of Genuine Bayer Aspirin, Fleischman's Yeast Cakes, Lady Esther's Wonderful Face Cream, Eno Effervescent Salts, all the best gasolines and motor oils, and of that great rejuvenator of the human system—Crazy Crystals!

And now a few words to the younger members of the Society. After forty years in the practice of medicine, I am more than ever convinced that the greatest thing in medicine is not surgery, or any specialty, or any particular form of treatment, but diagnosis.

You all know that to make a correct diagnosis is often most difficult, sometimes impossible even with all our wonderful modern instruments of precision, and you can, perhaps, imagine how much more difficult it was forty years ago without them.

Then we had to depend almost entirely upon physical examination and symptoms, and I still believe every patient is entitled to a thorough physical. So I say to you use your eyes, your ears, your fingers, and above all your heads, and then use the x-ray and the laboratory to prove or disprove your findings.

Sure, we all make mistakes, and will continue to do so, but mistakes should never be made through carelessness, neglect, or lack of proper examination. You know, also, that nature often comes to our rescue and sometimes our patients recover in spite of a faulty diagnosis or improper treatment.

Several years ago I had a male patient, age about seventy, who was very ill with influenza and pneumonia. The prognosis

was bad and in my opinion was made more so by the mental attitude of the patient

When I asked him, on my daily visits, how he was feeling, his answer was, "Well, doctor, I am not feeling so good today I know I am going to die and I can't see any use of your calling, for I think I can die quite as comfortably without you as with you"

After receiving this answer for several mornings in succession, I said to him, "All right, John, if you know you are going to die and are determined to do so, why go right ahead and die I don't think anyone will care very much anyhow" Well, I did not get my honorable discharge from the case, as I expected, and the very next

morning the patient stated that he was feeling much better and he continued to improve and make a nice recovery

Yes, the man recovered and this is the way he got back at me for giving him that shock, when he was so ill

I called to see him one morning after he was able to be about the house, when the following conversation took place, I said to him, "Good morning, John, how are you today?" And his answer was, "Oh, I am feeling pretty good today," and continued, "You know doctor, I have been thinking it certainly is remarkable how much *Nature* can do for a feller" All of which goes to show that some of our patients give nature due credit for their recovery

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., D.R.P.H., *New York City*

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Who is Who in Driving

I know there are many intoxicated automobile drivers and that they are dangerous on the roads. But when I drive my old car I cannot help thinking of some of the mental patients who sit at the wheel and imperil lives. And sometimes those belonging to the borderline or transition cases can be just as obnoxious as the advanced patients. Nay more, because the latter rarely handle machines.

A plumber suffering from mild *paranoia* in the form of persecution ideas had to drive every day a small truck with tools and pipes to the buildings where his men happened to work. He had moments of fear when he imagined that some enemy was coming in the car opposite or alongside his own. Then he often felt like running away, that is like making a quick turn to the right or left regardless whom or what he might meet or crush. He was still able to control his desire and only stopped slowly at the curb and waited till his vision would vanish. But some day he might be unable to master himself.

A wealthy young student who, in addition to his frequent drinking orgies had pronounced *schizophrenic tendencies* and all

sorts of anxieties, drove his car at all hours of night or day. He had no license because he could never pass the test and hated to employ his chauffeur not wanting him to know where he was going. One day, when his auto was in the repair shop, he borrowed a poor colleague's dilapidated car with bad brakes. That put him in a furious mood. He was not aware that the gasoline reserve in the tank was very low until the vehicle made a stop in the middle of the road and in such a manner that it violated all the traffic rules. He thought that somebody was playing him "a dirty trick", as he explained later, and, jumping out, he began to run until he was injured by another car.

A man of fifty who could never sleep at night because darkness brought him *delusions*, slept in the day time, but insufficiently, owing to his business. One day he dozed off while driving and awoke on the sidewalk where his car, after careening and breaking a newsstand and some windows, had spiled him out. Only then he consented to consult a physician and the latter sent him to a psychiatrist.

Two poor boys, working in a summer

camp, had to go nightly to the city to buy food in the wholesale market, so that they could be back very early in the morning. They were overworked and forever tired. One of them, the normal one, not doing any driving, always slept on the truck. But the driver was a *psychoneurotic* patient and constantly preoccupied with his thoughts. He often failed to hear somebody else's horn or to notice signals. He had many minor accidents until one night he smashed both his truck and an oncoming car, killed a passerby and, together with his partner, was knocked against a wall. They were both severely wounded.

A *hallucinatory* boy of twenty-one was a taxicab driver and only with great difficulty did I succeed in making him change his occupation.

A very young man with musical and literary leanings was employed in an art store in a provincial town. He had to deliver decorative and other objects by auto. But he was one of those atypical, indefinite or unclassified *psychopathic personalities* in whom it is difficult to predict what they might do under unusual circumstances. His mother had brought him to the clinic the first time. But the second time he came alone and said he had lost his job because he had made a mistake in driving. He was happy, though, because "from now on he would have time to tackle the 'Kreutzer Sonata.'" I naturally thought of Tolstoy's story with that name, as it reminded me of my own adolescence when this thrilling book had to be read in secret. But he corrected me at once by taking out a violin from under his overcoat and beginning to play with great skill and with the proper enthusiasm the first movement of Beethoven's famous *Kreutzer Sonata*—without accompaniment, of course. It was enrapturing. However, his normal state ended there. As he came to the *andante* he jumbled up the notes and mingled them with some imaginary and meaningless jazz. To my questions he answered that his employer had sent him with some original framed canvasses, after cleaning them, to their owner, who was living in an out-of-town mansion. The boss had enjoined him to be extremely careful as those were very valuable and expensive works of art, which made the boy particularly tense. If anything happened to them he would be held responsible. The story of Mummichus came to mind, the ignorant and uncouth Roman General who, at the conquest of Greece and during the transportation of great marble sculptures from Corinth to the boats bent for Rome, seriously threatened his soldiers that, if they broke any of the statues, they

would have to remake new ones. Well, our patient did not reach his destination. Passing near an insane asylum at the outskirts of the town he was frightened, as it often happened to him, that he might be interned there. Then he had the accident which damaged the pictures.

An inspector of newsstands for an important metropolitan daily, has to see the newsdealers of one section of the city, listen to their complaints and improve the distribution of his paper. He drives a car supplied by his employers. A quiet, unassuming, not talkative person. Married, having a few children. In the last six months there seemed to be danger of his losing his job—or he imagined so. He worries about his family and his fears have changed into a real *manic-depressive* state. In that state, he drives his auto for eight hours daily. There are moments when he does not know what he is doing. His movements are partly instinctive. It is true that the mind can do a good deal of automatic thinking, but he has had several "minor" accidents. The major one is due any day.

A Public Enemy

Mrs X is greatly excited. She bites her finger nails, throws things about, shivers at the least noise and has a hand tremor that makes her drop objects and break glasses and dishes. She always expects something bad to happen. She is more restless when anybody in the house is late in coming home. Then she cries, walks fast back and forth in her room, wrings her hands and bites her lips to the blood. But when her husband returns later than usual she is, of course, in even a worse condition. She often goes to the window and bends perilously down so that she has to be held not to fall over. Or she lies face down in her bed, tears the pillow or pulls her hair until she actually pulls out a good deal of it.

However, when her husband finally arrives she quiets down immediately and is as suave as she can be, although a few minutes before she had been tense to the breaking point.

In her constant impatience she, who used to be a model housewife, is now entirely incapable of doing her work. Fortunately there are no children.

Nothing in her family history, nor in her own past can explain her present mental state.

Is there a subconscious desire that her husband never return when absent? A fear that he may come home?

Let us see

This patient has felt that way only a short time—the last few weeks. There was never any indication before that she was unstable or unadjusted. There was not even the common complaint of “nervousness.”

What has happened a few weeks previously?

Her husband, a successful salesman, has been told by his firm that he will be advanced within a month. His salary will be raised and, instead of visiting customers on foot, through street cars, elevated and subway trains—the story happens in New York City—he will be given an automobile. Can he drive? Yes, but he has avoided it in the past, that is since he is married. His wife, our patient, has not allowed him to do it. Why? She does not answer.

I talk to her husband. He is ready to accept his employers' offer, as soon as they make the necessary arrangements, which will be in a few days.

With great difficulty, after much diplomatic and detective work, I discover that he is suffering from an illness of which there is no external sign, nor is it shown by an examination. Then I guess it. I tell him

“You are an *epileptic*”

He does not reply. No answer is an answer.

The rest is easy. I see them both together and I learn that “as far as he can remember he had had very light attacks of unconsciousness.” There were only three people who knew about them: his mother, now dead, his wife and he. They were both very careful to hide his illness. It was a deep secret. They thought they should not reveal it even to a physician.

This man's seizures came “in the morning only, soon after he gets up.” They were of very short duration and they gave him a brief warning, which apparently was not always concrete enough, as it did not interfere with his cutting his skin if they happened while shaving. As a matter of

fact, after an exact investigation, I find big razor scars and signs of tongue-biting. During the day too, when he is out on business he has, he confessed later, under pressure, momentary mental *absences*, from which he emerges quickly. “That has never amounted to anything,” he assures me.

“That may be so, but it is not compatible with driving a car anywhere, particularly in the busy city streets. If you do that, you become not only your own enemy, but a public enemy.”

He reiterates the great advantages for him in accepting the new position. Some young brothers, orphans, depend on him. So does his grandmother.

There was, of course, the inexorable, relentless economic question mixing into the private affairs of this man.

My reasoning with him, at first, my “forbidding” him strictly, afterwards, to drive a car, seemed to make but little impression upon him. In fact, it left him unchanged and cold, or rather hostile to me. When I hinted, however, that it might become my duty to denounce him to the proper authorities—although I felt that really I had no idea whether they would heed me—I got a response.

He looked to his wife and she lifted her eyes to him.

Then he took her hand.

“What'll I say to the boss?”

“You'll find some excuse,” she answered.

Her bosom heaved up and down and she had a tear at the corner of each eye. Her cheeks reddened. Clearly, she was greatly stirred, but not in the old way.

She was cured. From then on she behaved in her usual, healthy manner.

This is a story with a happy ending. But it could have been otherwise.

By the way, who knows how many drivers are epileptics especially since a large percentage of the population is effected with epilepsy or epileptoid states or equivalent?

611 W 158 St

PARRAN SEES LONGER LIFE

The average length of human life could be stretched another ten years, Dr. Thomas Parran said in Washington the other day, if advantage were taken of available medical knowledge.

Dr. Parran, surgeon general of the Public Health Service, said that in the last eighty years the average life span of men has increased from thirty-eight to sixty-one years and of women from forty to sixty-four years.

“I feel confident that another ten years could be added to the life expectancy,” he said, “entirely aside from the possibility of discovering an effective preventive for cancer or major heart diseases.”

“Great progress in reducing the incidence of heart disease will be made in the present drive to control and eradicate syphilis, since syphilis is the cause of a large percentage of heart ailments,” Dr. Parran added.

EDITORIALS

Charles Howard Goodrich, President

The Medical Society of the State of New York looks with a great deal of pride and satisfaction upon its choice of Dr Charles Howard Goodrich as its President for the ensuing year. An active worker for organized medicine since 1919, he has held office in the County of Kings and in the State Society, during the tenure of which he did yeoman's work. As chairman of the Committee on Economics, he was responsible for the initiation of many important phases of this vital problem and he served the Society well as Treasurer and as member of its Executive Committee.

His career as a practicing surgeon has been a notable one and the experience derived from his community interests will contribute to the Society in its relations with the public. He brings with him to office a mature knowledge of the requirements of medical practice as it affects the laity and the profession alike and so will draw these two closer toward a common viewpoint.

Dr Floyd S Winslow, who served so conspicuously in the interests of the profession, could be succeeded by no one more able to "carry on."

True for All

The Report of the Hospital Survey for New York has as much significance for the rest of the state as for the Metropolitan Area. The conditions encountered in that region, with its large cities and small towns, its millions of people and hundreds of hospitals, do not differ materially from those found elsewhere in New York State.

Certainly the status of physicians serving the sick poor is the same. Less than 2½% of the 13,433 practitioners who work in the wards and clinics of New York City and its suburbs are paid for their time and effort. The percentage is not much different elsewhere.

Two-thirds of approximately 50,000 hospital beds in the Metropolitan Area are allotted to ward patients. These free and under-rate facilities, from which the physician receives little or no income, are in constant use. The third on which he relies for earnings enjoys an annual occupancy of only 50%. This, too, with but slight variation, is the experience of practitioners everywhere in New York State today.

On the basis of these figures, the Survey Committee has done no more than justice in urging hospital authorities to cooperate with their medical staffs in an effort to procure compensation for the

latter's service to the needy sick. In the Metropolitan Area, alone, the value of this free service has been estimated to be over sixty million dollars a year.

Double this sum and the product will not be excessive for the state. The movement to pay the private practitioner for his work in wards and dispensaries should be organized on a state-wide basis, with state as well as local hospital associations cooperating.

Another feature of the Report holding interest for practitioners everywhere is the Committee's advocacy of home treatment of the sick poor by their family physicians. Dictated by efficiency and economy, this principle was embodied in the recent Ehrlich bill. The profession will again seek its adoption at the next session. With the support of responsible hospital organizations, it shouldn't fail.

The Report of the Hospital Survey for New York is more than a picture of the Metropolitan Area. It is a cross-section of medical practice in relation to medical institutions throughout the state. It has a message for physicians everywhere.

Hints for Next Year

Considering the intense partisan struggle underlying the 1937 legislative session, medicine did not fare badly. If none of its major undertakings succeeded, at least its adversaries were decisively rebuffed.

Both Assembly and Senate showed themselves able and willing to resist political pressure in defense of the public health and the integrity of medical practice. Their uncompromising rejection of compulsory health insurance and osteopathic expansion, their refusal to entertain a chiropractic plea, gave warning that New York State will not tolerate tampering with its medical practice laws or standards of professional service. By defeat of the anti-vivisection and anti-vaccination bills, scientific experimentation was upheld and wide distribution of its benefits encouraged.

Such defeats as the profession en-

countered are not without their lesson for the future. The physicians' and nurses' lien bill, although sound in principle, succumbed to technicalities raised by various bar associations. Their criticisms should serve as a guide to the formulators of next year's bill.

If the American Foundation's report had been issued sooner, the fate of the Steingut central registry bill might have been different. The unanimity of opinion on the need for establishing indigence lends impressive support to this measure.

The same is true of the Report of the Hospital Survey for New York in relation to the Ehrlich bill for domiciliary treatment of the needy sick by the family doctor. The statistics cited and the recommendations made amply justify the profession's demand for this law.

With such support at hand, physicians should recommence the campaign for these measures now. The return of senators and assemblymen to their home territory affords an unequalled opportunity for personal contact and discussion.

The months slip away quickly. Before we know it January first will be here again and the 1938 Legislature in session. Shortly local elections will absorb the attention and energies of politicians. *Now* is the time to lay the foundation for a successful medico-legislative program for next year.

Dr J Vander Veer

As we go to press we learn with regret of the passing of the widely known surgeon and former President of the State Society, Dr James N Vander Veer. He had been critically ill for a week, although he had not been in good health for a long time.

During 1929 and 1930 he served us as President. He was graduated from the Albany Academy, and later from Union College and the Albany Medical College.

He was an active surgeon, until the end, at the Memorial Hospital in Albany.

He was a director of the Bender Laboratory and St Peter's Hospital. During the war he served overseas with the rank of lieutenant colonel. For a long time he has been active in the affairs of our Society, and his activity has also covered many other fields, Masonry, the Presbyterian Church, the Holland Society, the Society of Mayflower Descendants, Dutch Settlers, and the Association of Military Surgeons, to say nothing of the Albany Rotary Club. All this gives evidence of his manifold interests. He was a charming gentleman and a delightful companion.

CURRENT COMMENT

"A MILLION TOOTHBRUSHES could be sent into a backward community, but they would be of no use until the people were sufficiently able to feed themselves properly and to preserve their teeth." Thus declared Dr Charles Gordon Heyd recently.

"THE PHYSICIAN who is not a member of his medical society may believe that he has sound reasons for not belonging. Yet such a man does well to review the advantages of membership every once in a while. More than ever before are the local doctor's professional connections a matter to be argued and discussed over the back fence." * * * "Far from compelling people to accept any single system of treatment, the basic science laws place the cachet of respectability upon all licensed practitioners of whatever sect. It is not the fault of the laws if, once a man has qualified in the basic sciences, he is able to perceive the fallacy of cult theories and prefers to cast his lot with orthodox medicine."—Two "Sidelights" from *Medical Economics* of May, 1937.

"* * * Let the government, national or community, care for the indigent sick, or the necessarily unemployed but let physicians practice medicine, let them rule as to how medicine should be practiced and let the medical profession pursue the tenor of its ways undisturbed by the interfering latti whose ignorance of medicine is equalled only by the supreme self-conceit of its meddling egoists." * * * The trouble with

state medicine of course is that it is far more 'state' than 'medicine' * * * We must meet organization with organization. As individuals we can do nothing and may be forced to dance to the tunes of sociologists and reformers." Excerpts from the editorial in the May 1937 issue of the *Illinois Medical Journal*.

"* * * The real issue is not state medicine, but what kind of state medicine—whether government shall more properly concern itself with the relief of one group of the population, the underprivileged, in illness, or whether it shall concern itself with better health for all groups of the population, the privileged and the underprivileged alike." A statement of one of our instant problems by Miss Esther E. Lape of the American Foundation, whose report on medical care in this country was recently published.

"WHAT WOULD HAPPEN to the health of the nation, if research in medicine were directed by and for those who wished to take over the physician's practice for political or economic purposes?" Dean Carl W. Ackerman of the Pulitzer Graduate School of Journalism, poses this question, and is quoted by the *St. Louis County Medical Society Bulletin* for May 7, 1937.

"* * * I expect to see the day and it won't take more than twenty years when the Government sees to it that one-third of the population which is as present insufficiently clothed and fed will have a decent living standard." * * * We've just made a beginning. We haven't done anything about sick pensions, pensions for widows, and the like. But we're going to do something about them." * * * This is going to cost money. It's going to cost plenty. There's no sense kidding ourselves about it." Some significant impromptu remarks made by Harry L. Hopkins, Federal Works Progress Administrator.

DR. FREDERICK M. ALLEN wrote to *The New York Times* under date of May 14th in which he "makes out the best possible case for a continuance of medical research along the traditional lines." According to an accompanying editorial in the *Times*, Dr. Allen has written an answer and an explanation to those "who are convinced that we would progress more rapidly in our knowledge of cancer if planning, organiza-

tion and competent direction were substituted for the present laissez-faire policy" We quote Dr Allen in part

"Medicine is not backward. It has advanced fully as fast as any other branch of knowledge, and physicians have reasonable justification to claim that they know their business better than outsiders * * *

As far as can be ascertained, none of the critics has a single suggestion for any line of attack upon cancer that is not already included in research now in progress, neither can these critics name a single development in the entire domain of science that is not instantly seized upon by cancer investigators if it seems to have any application to their subject

Practically all medical discoveries have been made by individuals or small voluntary groups. The idea of an organized mass attack therefore lacks basis in past experience * * *

If the critics can find the money and form an organization for such a group attack upon any phase of the cancer problem, they will undoubtedly contribute valuable new information and their aid will be welcomed by every cancer worker. But cancer and most medical problems differ from industrial problems in that nobody knows which line of attack will be most effectual and directors of cancer labora-

tories do not feel justified in concentrating their limited resources upon one phase at the cost of suppressing progress along other lines which are widely different but equally promising * * *

The great majority of medical investigators work on small salaries or none, and all their discoveries are given to humanity free. Secretiveness, selfish ambitions, and particularly the evil known as 'politics' belong to institutional organizations, rather than to the individual investigators, and they tend to increase, along with regimentation and barrenness, according to the size of the institution and its endowment"

Another slant on the question, presented by the *Times* " * * * If we were to assume that because the past holds out no promise in attacking scientific problems along new lines, there would be an end of all original research

Medicine has become a complex of pathology, chemistry, physics, anatomy, bacteriology, mechanics, genetics, cytology, psychology and half a dozen more sciences. It is about the last discipline that can afford to ignore benefits that are sure to follow the organization of all these branches of knowledge in research laboratories dedicated to the task of discovering the fundamental causes of diseases that still perplex and ways of conquering them"

Syracuse

To the Editor

Highly complimentary words regarding the Maternal Welfare Campaign in Syracuse made by the Maternity Association of New York City and reported in the May 1 issue of the JOURNAL put Syracuse back on the banks of the Erie Canal and shoved the town some fifty miles eastward, thus removing it from the Onondaga Valley and setting it down in the Valley of the Mohawk

The appreciative article is accepted as a fine gesture, but, please, now that the trains are out of our streets, may we be moved back to our own Valley and placed on the Erie Boulevard?

Sincerely yours,

FREDERICK S WETHERELL, M D
May 4, 1937

We hasten to reduce the dislocation in the hope that business may go on as usual in Syracuse and that we may be made as welcome in that hospitable city as we have in the past—Editor

York City on April 20. Other officers are Vice-Presidents, Hyman Lieber, M D, Henry S Ruth, M D, Brian Sword, M D, Secretary-treasurer, Paul M Wood, M D

Presidential Address

We Look at Ourselves

*President's Address, 131st Annual Meeting, Medical Society of the State of New York,
Rochester, May 25, 1937*

FLOYD S WINSLOW, M D , Rochester

"O wad some Power the giftie gie us
To see oursels as ithers see us!"

* * *

Perhaps the doctor is likely to forget that while he is looking at patients, patients are also looking at him. He is a trained observer. The habit of inquiry is so ingrained that wherever he goes, be his mission professional or personal, he is constantly studying and evaluating human beings. Now the people with whom he comes in contact are also studying and evaluating him. Not always with so much skill. Sometimes with surer intuition.

Let us not be too quick to say that the crude opinion formed of the doctor by the crowd is an unworthy opinion or one meriting only casual attention. "The learned and studious of thought," said Ralph Waldo Emerson, "have no monopoly of wisdom. Their violence of direction in some degree disqualifies them to think truly. We owe many valuable observations to people who are not very acute or profound, and who say the thing without effort, which we want and have long been hunting in vain. The action of the soul is oftener in that which is felt and left unsaid, than in that which is said in any conversation."

Today it seems to us, who are doctors, that the eyes of the world are turned upon us. We have invited it. We must not discourage it. In our efforts at self-improvement we have been free to comment on our own faults and we must not deny this privilege to others. If knowledge has increased, and it has increased, if skills have improved, and they have

improved, if the code of honor has been raised, and it has been raised, this is due to our inveterate habit of self-analysis and acid criticism. Nobody outside the profession can possibly be so severe with us as we are with ourselves. Perhaps we do not point our barbs with the wit of Bernard Shaw or the sarcasm of H. L. Mencken, but we shoot at a truer mark—the target of our faults rather than our foibles. We have nothing to fear because the eyes of the world are turned upon us. There is nothing to hide. Misunderstanding always precedes understanding, and is easily dispelled if we trouble ourselves to dispel it. We should encourage those who speak in criticism. We look at them, they have a right to look at us. Let us sit down at the table with our critics, and discuss the flaws they find. Many of them may be flaws we also have found, and are taking steps to remedy, of which the critics are not fully aware. Some of the flaws are not blemishes at all, but only appear so through snap judgments based on insufficient facts. Let us discuss the whole of our problems with our critics, taking plenty of time to appreciate diverging viewpoints, to look at each other.

In such conversations we are sure to encounter the situation so well described by Oliver Wendell Holmes. He stated that when two persons are talking with each other there are really six, not two. You as you think you are, I as I think I am, you as I think you are, I as you think I am, and of course, both of us as we really are. What two persons must do first when they enter into conversa-

tion is to find the least common denominator between their personalities *It can always be found* It can be quickly found if both come in a spirit of willingness to look at each other If I may be allowed to quote again from the great Transcendentalist I would like to use his words "In all conversations between two persons, tacit reference is made, as to a third party, to a common nature

In dealing with my child, my Latin and Greek, my accomplishments and my money stead me nothing, but as much soul as I have avails"

To look at ourselves means to make a comparison with what we hope we may be This attitude has been characteristic of the medical profession since the earliest days of history Not alone of the medical profession, it has been characteristic of the race Man envisions his ideal state, he uses the means he thinks will help him attain the good life, he moves toward the betterment of himself as a corollary to improvement of his environment, he sees a light burning and follows it Ours is not the only light Others burn brightly in the hearts of men Even in days of confusion such as we are living in at present, it seems to me that our unrest is due to the fact that we all look through a different glass window and see the light in varied form and color It is, if we but knew it, the same light, the light of truth, though no man has eyes to see it naked By different paths, we approach the same goal There is an amazing correspondence between Emerson's Over-Soul, Swedenborg's Grand Man, and Freud's Super-Ego

So men seek the good life in different ways because men are different Constantly we must stop to ask if ours is really the good life We may become so immersed in technics that our very acquisition of knowledge retards the developments of wisdom As we become more efficient we can easily become less effectual We seek in vain today for the counterparts of Oliver Wendell Holmes, Sir William Osler, William H Welch, who moved so ably with freedom among

the crowd and with ease among the elect, bringing to the one what was needed from the other, helping all of us to see ourselves as others see us These men were not too busy to give time to the humanities How many of us do as Osler did, and devote a period of each day to our Greek? Few indeed seek that culture which means an acquaintance with the best thought of the great minds of all ages The minute we leave college, it seems, we cease the broadening process and begin the narrowing one President Conant of Harvard recently told a graduating class, "Choose your rut now, you will be in it for thirty-five years"

The doctor is indeed fortunate that his calling brings him in contact with people of all sorts This saves him from falling too deeply into the rut which he must follow all his life It gives him the opportunity to draw upon many sources of inspiration, it tests his mettle daily, it refreshes his viewpoint, it challenges instantly his attitudes and aspirations But there is a handicap involved in this contact of which he may not always be aware He comes as a savior of the sick He is as God His word is law There is always a tendency for a man endowed with absolute authority in the realm in which he is proficient, to carry that feeling of power into realms where he is not so proficient He, himself, must provide the check and balance here, and if he does not, the world will provide it for him From time to time we should take stock We must look at ourselves and try to see ourselves as others see us

More is expected of us than that we go about questioning men We must answer questions, too Socrates was called the gadfly of Athens because he asked questions and seldom answered them I often wonder what would have happened to Socrates if he had answered the questions which he asked, if people had questioned him as intelligently as he questioned them Perhaps he would have escaped the hemlock I do not doubt he fully knew, and did not care, how uncomfortable he made other people feel

He described himself as a midwife practicing on the souls of men when they are in labor, and diagnosing their condition, whether pregnant with the truth or with some "darling folly." He forced people to take a good look at themselves. They resisted, not what they saw, but the man who made them see it. This pain would have been spared them had they made the effort for themselves to answer the questions which he asked. So if we are to look at ourselves calmly and to good

purpose, we must first take thought to see ourselves as others see us. Our ideal, call it the Over-Soul, Grand Man or Super-Ego, may be modified to add new colors to the picture we hold up before us of what we would like to be. Then it will be unnecessary to join in the lament of the parodist who turned Burns' couplet neatly inside out

"O wad some Power to ither's gie
To see Myself as I see Me!"

PNEUMONIA CONTROL PROGRAM

The following letter was recently sent out by the Federation Health Committee, the Home Demonstration Agents' Committee and the College Committee to Home Demonstration Agents, County Executive Committees, and County Health Committees

Dean of the Colleges of Agriculture and Home Economics Director of the College
CARL E. LADD FLORA ROSE

NEW YORK STATE COLLEGE OF HOME ECONOMICS
AT CORNELL UNIVERSITY, ITHACA, NEW YORK

*Dear Home Demonstration Agents, County
Executive Committees and County Health
Committees*

Your interest in the problem of pneumonia control has undoubtedly been aroused by the reports you have heard of the campaign undertaken in Franklin County this past year and by the articles written by Dr. E. S. Rogers, which appeared in the Health News Letter of the State Federation of Home Bureaus. Pneumonia is a statewide problem. Twelve thousand (12,000) deaths occur in New York State every year as a result of pneumonia, three-fourths of them people under sixty-five years of age. This ranks as the third highest of the causes of death and is far and away the highest cause of infant death.

This large number of deaths can be reduced by methods now thoroughly understood by the medical profession. Lay education is one of the most vital steps in the program for control.

A recent meeting of the health committees of the New York State Federation of Home Bureaus, the New York State College of Home Economics and the New

York State Federation of Home Demonstration Agents, was held in the office of the State Department of Health in Albany. The Federation was represented at this meeting by Mrs. C. S. Goodwin, the College by Miss G. Dorothy Williams, and the Home Demonstration Agents by Miss Odessa Dow, Miss Mabel Milhan and Mrs. Natalie D. Crowe. The State Department of Health was represented by Dr. E. S. Rogers, in charge of Pneumonia Control, and Mrs. Ethel M. Hendriksen, Field Instructor in Public Health Education.

As a result of this meeting the health committees suggest

1 Where there is sufficient interest in a county in pneumonia control, it would be well to include it in next year's extension program.

2 Many county medical societies are preparing to organize campaigns which would include lay education. This presents an opportunity for Home Bureau groups to build up a valuable relationship and a cooperative program. Since this is a highly scientific subject, this should be a cooperative project with the County Medical Association.

3 The plan that was used so successfully in Franklin County may be adapted to local situations. That included four lessons. The course started with a training school for local leaders which was given by Dr. Rogers and the District Health Officer. In addition to

giving material for Lesson I in the local units on "What is Pneumonia and Why is it a Public Health Problem," the leaders were also given general background for the whole series. Lesson II on "Nursing Care of Pneumonia in the Home," was given in the local community by public health nurses. Lesson III was a summary and survey of local facilities and a constructive consideration of personal and community responsibility. In addition, they had mass meetings under the auspices of the District State Health Officer, who is in a position to give much valuable advice on local conditions. Whenever it is possible, a local physician should present the introductory material given in the first lesson in each unit. The local leaders will need to be carefully chosen in order that there shall be perfect co-operation with the local medical authorities.

It would be advisable to start these lessons in the fall so that the information could be broadcast in anticipation of the next pneumonia season, which begins in December.

If your county wishes to undertake such a series, the committee recommends that

1 Your home demonstration agent and health committee meet with the County Medical So-

cety or its representative, to discuss your plans and obtain their consent and approval. We are enclosing a list of the presidents of the County Medical Societies. Many of these organizations include a chairman of public education among their officers.

2 Write to Dr. E. S. Rogers, State Department of Health, Albany. He will be glad to help you adapt his plans to your county situation and give you dates for your meetings.

3 Notify the chairman of the Home Bureau Federation Health Committee, the College Health Committee and that of the Home Demonstration Agents of your plans so that each of these groups may give you any help you may need.

HEALTH "TALKIES" FREE TO ALL

The Healthmobile, the State Health Department's traveling motion picture unit, has been completely equipped with sound motion picture projectors and is ready to put on up-to-date talking motion picture shows on health subjects. Talking slide film productions, specially projected health pictures synchronized with voice, are another new feature of the modernized Healthmobile.

This service is available without cost to any community within the State at the request of health officers, health organizations, and other responsible persons and groups. Because of the time and expense incurred in travel, individual engagements are not booked for the Healthmobile, as a

rule, except within reasonable distance of the central office at Albany. The usual procedure is to schedule a series of meetings to be held in a county or community over a period of a week or more, the meeting places being arranged by the persons or organizations requesting the service. The talking pictures have attracted large audiences giving excellent opportunity for a local speaker to present community health projects or to give a talk on some health subject.

Complete information concerning the Healthmobile service may be obtained from the Supervisor of Visual Instruction, New York State Department of Health, State Office Building, Albany.

THOSE LITTLE PHARMACAL ADS

The use of prescription forms supplied by pharmacists and bearing the pharmacist's name is considered unethical in Great Britain. A note displayed prominently in *The British Medical Journal* says "The attention of the Central Ethical Committee of the British Medical Association has been drawn to the fact that certain members of

the profession are using prescription forms supplied by a firm of chemists the name of which is printed at the foot of the form. The Committee considers it very undesirable that medical practitioners should make use of prescription forms bearing the name or the advertisement of any individual pharmacist or firm of pharmacists."

Economics

Medical Economics—Why?

S J APPELBAUM, M D, Rochester

Consultant in Medicine, School of Medicine and Dentistry, University of Rochester

In much of the matter appearing in various periodicals, both lay and professional, there is considerable discussion about medical economics, but altogether too little discussion of the subject itself. Consequently, much heat has been generated, but too little light to clarify the subject. On the contrary so much smoke has arisen that the subject is buried in obscure clouds.

If we will consider this problem in the same manner as we attempt the solution of a scientific problem, let us say, as you would attack a medical problem, certain questions will present themselves. I have asked myself these questions and propose to discuss them with you.

I

First Why is it that we have a question of medical economics in the United States?

Let us consider the maladjustments in medical economics as a disease, a disease, however, which not only has attacked the medical profession, but a disease with which the public is also afflicted. From this viewpoint, what are the etiological factors affecting medical economics? It is true we cannot conduct scientific experiments with controls in searching out such possible causative factors, but we can rationalize and attempt to come to some logical conclusions. Such an analysis of the problem might suggest possible remedies for the condition.

Has any change taken place in the character of medical practice, let us say, in the past twenty-five years? I can speak from personal knowledge of that period as I began practice in 1910. Has this change in the character of medical practice any relationship to the problem of the economics of medicine?

Perhaps one of the most important

changes has been a decrease in the demand for certain types of medical service, in part because of the remarkable advances in medicine with a consequent reduction in mortality and morbidity rates. A contraction of the field of private medical practice has taken place resulting in part from the application of the principles of preventive medicine. This contraction has four major causes.

1 Sanitation—sewage and drainage, protected water supplies and protected milk supplies.

2 Immunization—typhoid, diphtheria, scarlet fever, with efforts in other contagious diseases.

3 Modern care of tuberculosis—segregation in sanatoria.

These three causes together may be grouped under preventive medicine. The respective mortality rates for 1910 and 1935 in Rochester illustrate the results of preventive medicine.

Death rate per 100,000 population

	1910	1935
Typhoid	13 7	3
Scarlet fever	21 1	6
Diphtheria	16	1 8
Tuberculosis	157 7	13 6
Gastrointestinal	124 3	5 3

Total Death rate per 1,000 population

1910	14 54
1935	10 18
Over 1,300 lives saved in 1935	

4 Contraction of the field of private practice through greater use of socialized service, clinics and ward service.

In the decade from 1921 to 1931 the population of the United States increased about twenty per cent, but the number of patients treated in outpatient departments increased about one hundred and twenty-five per cent and the number of visits increased about one hundred and fifty per

cent. In 1927 twenty-five per cent of the population of the City of New York utilized outpatient departments. Less than ten per cent of this number were known to the Department of Public Welfare or voluntary agencies as indigent. Excepting teaching hospitals, twenty-five years ago ward beds comprised but a small portion of the average private hospital. At present, in the average hospital, the reverse is true. In recent years the number of days care given in the wards of the larger hospitals in Rochester was more than twice the number of days care given to private patients. In the combined Strong Memorial and Municipal Hospital at Rochester last year, thirteen per cent days care was given to private patients and eighty-seven per cent given to ward patients. What is true in Rochester is true over the country, to a lesser extent in smaller cities and to a larger extent in larger cities.

Some compensatory expansion of private practice has taken place during this period due to (a) immunization procedures and preventive practice in general, (b) workmen's compensation practice, (c) a considerable expansion in the field of surgery.

Reference was made to a contraction of the field of private practice through greater use of socialized service as exemplified by the increased use of clinics and ward service. This situation demands further analysis. Of course the obvious answer to this condition is that the past seven years have been lean years. We have been going through a period of depression. When we say going through, it is implied that as the depression had a beginning, it will also have an end. We all hope so. If you go through something, it must have both beginning and end. But this situation was true before the depression. Why has this happened? Of the many reasons for the contraction of the field of private practice through the greater use of socialized service three stand out as fundamental.

1 An increasingly larger proportion of our population has an inadequate income.

2 The pressure to maintain a high standard of living often prevents adequate provisions for medical care.

3 The increase in technical medical procedures in the past two decades, with a corresponding increase in cost for medical care, has increased the cost of medical service in the exceptional cases.

The first two given reasons are purely economic. I believe the consideration of the economics of this question is essential for a fuller understanding of the problem.

Now as to the income of the population.

The figures for the distribution of incomes for 1928 are easily accessible, but you must remember that as to incomes 1928 was a good year.

From the census report of 1928, the incomes of twenty-nine million families have been studied. The families average $4\frac{1}{2}$ persons.

Fourteen per cent had incomes of less than \$1,000.

The average wage per wage earner is between \$1,200 and \$1,300.

Fifty-five per cent had incomes of less than \$2,000.

This is a reasonable basic income adequate for the maintenance of a decent standard of living.

Seventy-seven per cent had incomes of less than \$3,000.

Six and one-half per cent had incomes of over \$5,000.

Less than three per cent had incomes of over \$10,000.

If your income is over \$10,000 then you are in a very select group.

If the minimum family income were \$2,000, and if the purchasing power of the dollar remained about where it is, there would be no occasion for this pressing problem of medical economics. In our ordinary economic relationships the ability to purchase goods or services depends on income. However, in the medical profession there is an effort to grade fees in accordance with ability to pay. Where there is no ability to pay, service is given without charge. When the purchasing power for service becomes lowered, as it has during the past few years, a corresponding inordinate increase in the demand for free medical service must be expected.

The group with little or no income, of course, presents the major economic problem, both to the taxpaying public, the voluntary agencies, and to the medical profession. Facilities for the medical needs of this group fortunately exist in the average community. Here in Rochester, where it is true, our standards may be higher than the average, fairly complete facilities exist to meet the medical needs of this group. To be sure they are not

met one hundred per cent but we cannot overlook the hardships under which the average taxpayer meets his tax bill and the difficulty of raising adequate funds for the voluntary health agencies. We have facilities for the care of the indigent in the home through a staff of city physicians. Adequate facilities for clinic care are present in the outpatient departments of the various hospitals. We have arrangements for supplying the reasonable medical supply needs, such as medicines, glasses, belts, corsets, trusses, orthopedic necessities, and dental care. Hospitalization, when indicated, is given not only to the indigent, but also to the large group of borderline cases, individuals who are able to meet all their other needs except hospitalization. I have referred to the local situation because I am intimately familiar with it. However, to a greater or lesser extent, these same facilities exist elsewhere.

Under normal conditions, the medical profession in conformity with medical ethics, considers it its duty to furnish free medical care to the indigent. However, during the past years, when as much as twenty-five to about fifty per cent of the population secures free medical care in one form or another, then we have reached a condition where we have a public problem and not merely a medical problem. When large numbers of people are in need of medical care, which they are unable to purchase for themselves, even if this medical care is not in each instance a matter of public health, nevertheless, the accumulated need of such care does become a matter of public health and as such should become a matter of public responsibility. To the extent to which private philanthropy is able to supply this need, to that extent public funds should not be used, but when the needs exceed the resources of private funds, then tax funds must step in to fill the gap. The frankly indigent are assumed as the responsibility of the local government unit. They are supplied with food, shelter, and clothing. Medical care is recognized as the fourth essential need and also should be assumed as a community responsibility. Clear-thinking, however, should differentiate between supplying the facilities for medical care and the supplying of the actual professional service. The great increase in free medical care to the indigent has resulted in a corresponding contraction in

the field of private practice. I do not know how long physicians should be expected to carry this community obligation. It is time to give thought to the question of some method of compensation to the physician for carrying this burden of community responsibility.

Another factor which has produced a decreased ability to purchase medical service is an increasingly rising standard of living. Things which in the past were considered luxuries are now considered almost essential, the automobile, the modern home with central heating and electrical refrigeration, the radio and the innumerable labor saving devices for homes.

Workers, even in low income groups, have been educated to desire and purchase these semi-luxuries. Publicity and advertising has created that mental attitude on the part of the consumer. In 1929 nearly two billion dollars, over two per cent of the national income and more than twice the amount paid to all physicians in this country, was spent on advertising. Workers have been encouraged, through partial payment plans, to mortgage their future earnings for these semi-luxuries, with the result that when the need arises for expenditures for medical services, there are neither funds nor other provisions for the payment for such service.

The third of the major reasons for the increase in socialized service is the increase in technical laboratory procedures in the exceptional cases with a consequent increased cost for medical care. I question whether I need spend much time on this problem. I need only refer to the use of the x-ray for diagnosis and therapy, the electrocardiogram, the determination of basal metabolism, the various and many chemical and cytological examinations of body fluids and secretions to indicate definitely what I mean. In private practice these services, frequently necessary, are comparatively expensive. Individuals, and often physicians, consequently, in many instances seek socialized service to meet this need.

Physicians as a rule are opposed to socialized medicine. What, no doubt, is meant, is State medicine. I question if physicians realize to what extent the practice of medicine has already become socialized, socialized in the sense that the service is furnished through public and private philanthropic funds. I venture to say that

fully twenty-five per cent of the ordinary office or home type care, and over sixty per cent of hospitalized care, is socialized in the above sense

So far I have discussed several phases of the problem of medical economics associated with the demand for medical service. I have indicated that there is a decreased demand for private medical service due largely to a contraction of the field of private practice. This contraction as suggested is due to public health activities, preventive medicine in private practice, and to increased use of socialized medical service. In discussing medical economics from the economic standpoint, it becomes essential to give consideration to the reciprocal factor to demand, which is supply.

II

This brings us to a second question. Has any change taken place in the supply of medical service in the past twenty-five years? Is this change a factor in the economics of medicine?

There are at present about 160,000 physicians in the United States, a ratio of about one physician to 780 population. In 1909 there were about 134,000 physicians with a ratio of about one to 570. On the surface then it would appear that we have a comparative under supply of medical service, the population having increased more rapidly than the number of physicians. However, it is of interest to note that the reverse is true in New York State. In 1898 the ratio was 790 and in 1928 it was 649. In Rochester the ratio at present is about 1 to 600. In 1910 there were 131 medical schools with 4,440 graduates. In 1932, as a result of a campaign for high standards in medical education, there were 76 medical schools, 66 of which are approved, with 4,936 graduates. In 1935 about 5,500 new licentiates were privileged to practice medicine. Annually about 4,000 physicians die. We have then an annual increment of about 1,500 physicians. It is interesting to compare the ratio of physicians to population in our country with a few European countries

Germany	1560
France	1690
Norway	1760
The Netherlands	1820
Belgium	1850
Sweden	2890

If our ratio were the same as in England and Wales, we should have 82,500 physicians, if the same as Germany 79,000, France 73,000, Sweden 42,500, but we do have 160,000.

This problem would be simpler if there were an even distribution of physicians throughout the country. However, the distribution varies greatly. California has one physician to about 480 people, but Montana and South Carolina about one to 1,430. About one-half of the total population of the country is in communities of 5,000 or less, but only about twenty per cent of recent graduates locate in such areas. The tendency in the past twenty-five years has been a concentration of physicians in larger centers of population. With this concentration of physicians in the larger centers, there has also taken place an increased tendency to specialization. Graduates are choosing specialties rather than general practice, so much so that the specialties in some instances are becoming overcrowded.

I stated that the ratio of physicians to population in the United States in 1909 was one to 570 and at present about one to 780, indicating that we have at present a comparative under supply of physicians. Such a conclusion, however, is quite fallacious. It would be based upon an uncritical consideration of associated factors. Statistics have a significance, but only if correlated with a background, a setting in which their true value is brought out. What are the correlated factors which have a bearing on the deductions which may be drawn from these figures? These are many. I referred to some of them when I took up the question of the demand for medical service. There has been a remarkable diminution in the prevalence of certain diseases which formerly kept physicians busy. There has been a great increase in the use of socialized service. In addition there has been a considerable increase in hospitals and hospital beds. In 1909 our total number of hospitals was 4,359 with a capacity of 421,065 beds. In 1931 we had 6,613 hospitals with 974,115 beds. During this period the

United States	780
Canada	1050
Switzerland	1250
Denmark	1430
England and Wales	1490

population increased about thirty-five per cent, hospital beds about one hundred and thirty per cent. During this same period there has been even a greater increase in clinic facilities. These means for centralized medical care reduce the number of physicians needed for the required service. During this period we also definitely emerged from the horse and buggy days. The automobile, the telephone, and good roads gives the competent physician a much wider area for service and make it possible for him to cover the needs of a much larger number of people. Interpreting the statistics then, in the light of concurrent factors, it can be definitely stated that we do not have an under supply of physicians, but a decided over supply. Many authorities state that a desirable ratio in the United States would be one physician to 1,000 to 1,200 population. If this is true, and it is my belief that it is, then we at present have a surplus of about 30,000 physicians and we are adding to this surplus about 1,500 annually. We have, then, relatively more physicians than are needed to provide an adequate medical service. The supply of service is out of line with the demand. Medical service is in conflict with a fundamental economic axiom.

III

It is quite unnecessary to go into the question of the cost of producing medical service, that is, the cost of education and the overhead cost of delivering medical service. These factors are beside the point. As to income, it is of interest to note, because it has a bearing on the problem, that even in prosperous times about fifty per cent of the physicians of the country had a gross annual income of \$3,800 or less, and that twenty-five per cent had a gross annual income of \$2,300 or less.

What conclusions are we warranted in drawing from this rather brief and sketchy consideration of the economics of medicine, from this economic consideration of the problem of supply of and demand for medical service? What suggestions can be offered to remedy this unbalance of demand with supply? Necessarily such suggestions, viewing the problem as economic, should center themselves in relationship to supply and demand. What can be done to increase the demand for private medical service?

What can be done to decrease the supply of medical service so that the supply will not excessively exceed the demand?

First, let us consider what cannot be advocated. This is so apparent and fundamental that merely reference to it indicates its undesirability. We cannot advocate any contraction in sanitary and public health measures. Such activities and all activities of preventive medicine regardless of their effects on the economics of medicine, should be expanded to the fullest extent. The interests of the public are of greater importance than of any one particular group. However, insofar as it is consistent with efficiency and with the attainment of the desired objectives, as much of the programs of preventive medicine as can be carried out through private practice should be so carried out.

There are definite measures which can be taken to improve the economics of medicine. What can be done to increase the demand for private medical service? I have suggested that the high cost of diagnostic procedures do have an adverse effect on private practice. It diverts private practice into socialized channels. These most common procedures are x-ray, basal metabolism, and electrocardiograph studies, and various chemical and cytological examination of body fluids and secretions. I am questioning if it would not be desirable to make such facilities more freely available to the physician in private practice for private patients of the low income group. Early diagnosis and indicated treatment often is delayed because frequently such examinations are not made or are put off. The cost is too high. It is not clear in my own mind whether such activities should be carried on as an extension of existing clinic facilities, or of public health activities, or as projects fostered by privately endowed funds. I believe this entire question deserves careful consideration.

Can anything be done with reference to the much complained of abuse of free clinic care and free medical care in the hospital wards? I am certain that the enforcement of more strict regulations governing the admission of patients to such services will in a large measure correct this abuse. There is no reason why anyone able to pay a reasonable private fee should receive free medical care, either in the clinics or in the

hospital wards. The care of such individuals should not be a burden on either public or private funds.

There is no possession which the individual should value as highly as health. Unfortunately he usually gives it that high value only when he lacks it. The public is prone to consider medical care, unless urgently needed, as a luxury. Can the public be educated to view medical care as a necessity with a sufficient appreciation for it to be willing to provide for it? Can anything be done to educate the public to maintain and seek health?

It is estimated that the total annual average national expenditure, both public and private, for medical care is about three billion dollars, somewhat over three per cent of the average national income. About 2½ billion is a direct expenditure by patients, of which physicians in private practice secure about \$800,000,000.00. Of the consumer's dollar consequently less than one per cent is expended for private medical care, about as much as is expended for patent medicines and drugs, less than is spent for candy and about one-half as much as is spent for tobacco. In his own interests should the consumer be educated to make a wiser distribution of his dollar? This is an economic problem which has a bearing on medical economics. Industry often creates demands for its products. It not only takes the consumer's present dollar, but also mortgages his future dollar. This matter of educating the public to seek health is a question to which the county, state, and national medical organizations should give more thorough consideration. It demands the coordinated efforts of organized medicine. An intensive educational campaign may accomplish much in creating an increased demand for private medical service. Such an effort would be fully warranted not only in the interest of the medical profession, but also in the interest of public welfare.

Now, what can be done to decrease the supply of medical service? Can anything be done to bring about a reduction in the number of physicians? Much can be done in that direction which would be of mutual benefit to the public and the medical profession. But this problem involves the entire question of medical education. Too many physicians are being graduated. We still have too many medical schools, *but*

not enough good medical schools. We have too many physicians, *but not enough good physicians.* Smaller numbers should be accepted into the entering classes of the medical school with more stringent standards relative to scholarship, character, and personality. Although the Medical School of the University of Rochester could accommodate an entering class of seventy-five, it accepts only about forty-five. This school recognizes this problem and is doing its share to meet it.

Graduates are going into specialties in too large numbers. From fifty per cent to seventy-five per cent of the recent graduates of the high grade medical schools are specialists. The curriculum of the medical school should lay greater emphasis on general practice and prepare its graduates for such service. They may need be advised in their selection of subjects and in the type of internship for this purpose. Emphasis on these factors will, no doubt, not only decrease the tendency toward specialization, but also result in a better distribution of physicians. Specialists tend to concentrate in the larger cities. The curriculum also should lay greater emphasis on preventive medicine and public health. If properly prepared, our young men could go to the smaller communities and sparsely settled areas with satisfaction to themselves and to the people whom they would serve. These men should be subsidized with salaries for public health work. The small towns and rural areas should have small hospitals sufficient for the areas to be served and roads adequate for transportation needs. A program of this character, if put into effect, would help greatly to solve the problem of the maldistribution of physicians and of the consequent inadequate service to rural areas. However, education of the public is necessary for such a program.

In relationship to this discussion, the population may be divided into three groups, a small group with good income with whom we need have no concern, a larger group of frankly indigent for whom fairly sufficient provisions exist, and a still larger group with medium income who are able to finance their ordinary medical needs, but who find it difficult to finance their extraordinary needs. A good percentage of this group do carry some form of insurance to cover such contingencies. It is estimated that during the average year about ten per cent

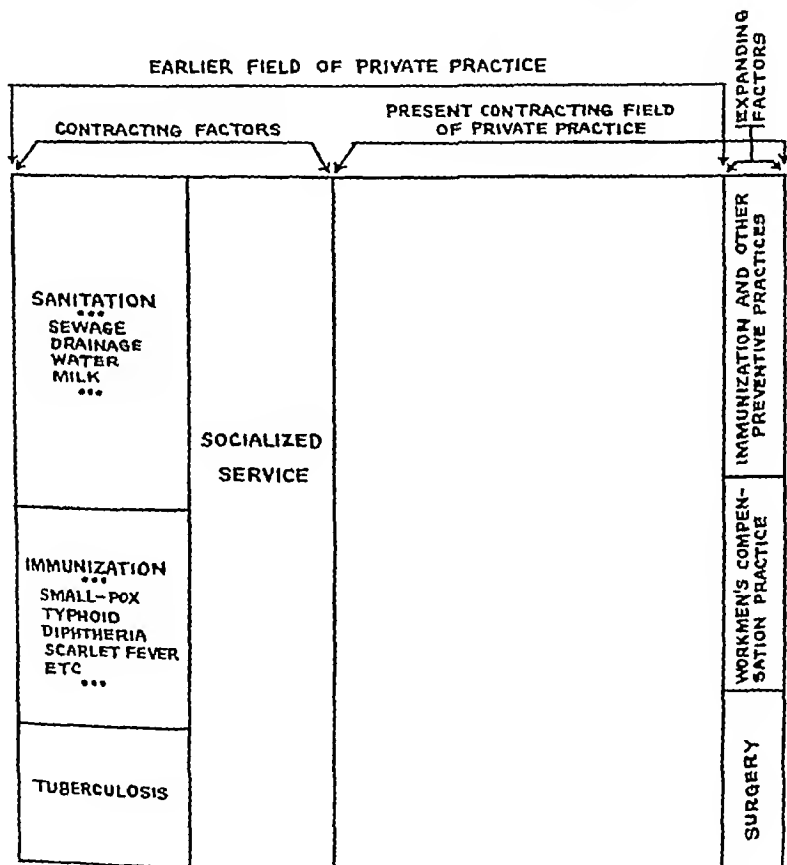

of the population suffer from severe illness. But it is rather difficult to estimate what portion of that ten per cent is seriously financially embarrassed by severe illness. Our attention is usually attracted to the unusual case.

IV

I have not referred to Compulsory Health Insurance. I have attempted to give a constructive analysis of the problems of medical economics as they effect both the public

But I believe that Compulsory Health Insurance is not for the good of the public. Under any compulsory scheme, a very large percentage of the money raised for health needs would be diverted to administrative purposes and to that extent would decrease the use of funds for direct health needs. Furthermore, in all these plans, both compulsory and voluntary, no provision is made for the care of the indigent. I understand that in Germany there are as many individuals employed in the administrative set-up for Health Insurance as there are physi-

CHART I—CHANGES IN FIELD OF MEDICAL PRACTICE

and the medical profession. But for the purpose of not seeming to evade this issue, reference must be made to that supposed panacea of the ills of medical practice and medical service.

In my opinion Compulsory Health Insurance is not a constructive solution of our problem. On the contrary, it is destructive. I know that its advocates are well meaning and have the good of the public in mind

cians giving service. Under any governmental program, the practice of medicine would be hampered with a large amount of clerical work, red-tape, arrogant bureaucratic regulations and supervision, and insidious demoralizing political factors. The practice of medicine in such an environment would not attract the right kind of men. Yes, the right kind of men would continue to go into research, but the results of

research are of value to the public only as they are intelligently applied to the public by the men in everyday practice. It is my belief that under government control the public would not receive as good a quality of medical service as prevails under our present system.

My basic premise on which the above opinion is founded is that medical practice should be organized in the interests of those receiving medical service. My disagreement with the proponents of Compulsory Health Insurance is based upon factors

inherent in the proposed fundamental change, chiefly, compulsion with the associated regulation, which basically are not in the interest of the public.

Some changes are no doubt necessary. Conditions are not perfect under the present system. They would be less perfect under a compulsory system. The cure, however, should not be worse than the disease. Let us not amputate a leg because the patient has an ingrown toe-nail, or, with all its implications, do a phallic amputation because the patient has a phimosis.

FERTILITY AND CONTRACEPTION IN NEW YORK AND CHICAGO

Raymond Pearl, Baltimore (*Journal A M A*, April 24, 1937), compared certain aspects of the reproductive histories of 3-951 women dwelling in New York City and 3,589 living in Chicago. All the women in both samples were living in wedlock, had been married only once, and were free of any recognized form of gynecologic disease. The age distribution of the women was substantially similar in the two groups. 1 The white women of the Chicago sample appear to be somewhat less fertile on the average as a group than the white women of the New York sample, whether measured by pregnancies experienced or live births produced. 2 Attempted contraception was more frequent among the Chicago than among the New York white women, the percentage of contraceptors being sixty-four in the former city and fifty-three in the latter. 3 As indicated by average lapse of time between marriage and the beginning of first pregnancy in primiparas, contraception as actually practised was more effective among the New York women than

among the Chicago women. The same result, but with a smaller quantitative difference, characterized the relative effectiveness of contraception as practiced by the multiparas, when measured by the criterion of the average number of years of married life spent in the nonpregnant state. 4 As measured by the degree of lowering of pregnancy and live birth rates per hundred years of exposure to the risk of becoming pregnant, the Chicago white women again were, as a group, to a substantial degree less efficient contraceptors than the New York women. 5 Reproductive wastage rates in general, and induced abortion (self or criminal) rates in particular, were lower among the Chicago white women than among the New York women. 6 The data from both cities indicate that women practicing birth control resort to criminal abortion more frequently than do noncontraceptor women. 7 Attempted contraception was less frequent and less effective among the Negroes than among the whites in the samples from both cities.

TO PENALIZE DRUG FAKING

Drastically increasing the penalties for counterfeiting drugs and medicines, Representative Virginia Jenckes of Indiana has introduced a bill placing enforcement activities with the "G-men" of the Department of Justice, according to the *Washington Herald*.

At the present time drug counterfeiting is only a misdemeanor, the penalty being a modest fine. The new bill makes such counterfeiting a felony, punishable by a fine not exceeding \$10,000 for each offense or by imprisonment not exceeding five years, or both.

Mrs. Jenckes says her legislation, making

manufacturers responsible for observance of the law, will build up a great confidence in the minds of the people.

She is sure of support from responsible manufacturers and distributors in her campaign to protect American homes from racketeers.

The proposal already has the active support of J. Edgar Hoover, head of the famous G-men, who has been eager to break up drug counterfeiting gangs. Mrs. Jenckes also revealed that she had conferred with Attorney General Cummings and Secretary of Agriculture Wallace before introducing the bill.

Public Health News

A Qualifying Course for School Physicians

The following course will be given at State College for Teachers, Albany, during the coming summer session and will occupy one hour daily for six weeks

Administration and Supervision of the School Health Service Program

2 hrs For superintendents, principals or other school administrators or supervisors who wish to become familiar with the desirable methods of medical inspection, hearing and vision tests and other special tests, follow-up service, securing treatment for remediable defects, the keeping of records and making reports

Actual typical situations will be analyzed, the problem discussed and programs developed to meet the special needs. Attention will be given to relationships between school officials and officials of health and welfare departments, social agencies, family physicians, etc.

Physicians doing school work and school nurse teachers with permanent or health teachers certificates will be admitted to this course. Credit for this course may be offered by physicians toward meeting requirements for certification as school medical supervisor

Instructors Dr Henry F Mace, Miss Marie E Swanson, of the State Education Department

In order to qualify for a full-time School Medical Supervisor's certificate other courses may be taken in the same session to make up the required six semester hours credit or this course may be taken now and other courses added later

Further information may be obtained from the office of the registrar, New York State College for Teachers, Albany or Dr H F Mace, Medical Inspection Bureau, State Department of Education

Diagnosis and Treatment of Syphilis and Gonorrhea

The Bureau of Social Hygiene of the Health Department of the City of New York wishes to announce the organization of a short, practical course in the diagnosis and treatment of syphilis and gonorrhea and other genitoinfectious diseases to be conducted by its own personnel in its own clinics

The salient features in the method of instruction are clinical teaching frequent demonstrations, very short didactic lectures, thorough clinical laboratory training, and above all individual instruction and practical experience by each student in all of the various technical procedures necessary in the treatment of these diseases

Only eight students can be accommodated simultaneously. It is desired that these students be young physicians, who have had internships in general hospitals. The time required is six two-hour sessions weekly for a period of three months, (divided into

four morning and two afternoon sessions) per week, or for those whose time does not permit of such concentration, three two-hour sessions weekly for six months (divided into two morning and one afternoon session per week). Total—72 sessions, 144 hours

All physicians who enroll for the course will be expected to attend punctually and regularly

At the successful completion of the course a certificate will be issued by the Commissioner of Health, attesting to the fact, officially, that such physicians have undergone the training as described above

Students will be selected on the basis of formal application and a personal interview with the Director of the Bureau of Social Hygiene

Application blanks may be secured from the Director Bureau of Social Hygiene 125 Worth Street, New York City

Special Pneumonia Control Appropriation

Growing public interest in pneumonia control culminated in the passage of the Schwartzwald-Hawkins bill which was scheduled to be signed today by Governor Herbert H Lehman

The program provided for the presence at the signing of the bill of the legislators who sponsored the measure, representatives of the State Committee on Public Health and Medical Education of the Medical So-

ciety of the State of New York, of the State Department of Health and of the Department's Advisory Committee on Pneumonia Control

The new law appropriates \$400,000 for use by the Department in the prevention, diagnosis, treatment and control of pneumonia. Of this sum, \$150,000 is made available to defray the cost of new construction needed by the Division of Laboratories and Research to meet the increased load of serum production. The law has been so drawn that it will be possible for the Department to aid New York City by furnishing pneumonia serums to supplement its supplies in the event of an emergency. The appropriation will be used primarily to finance the production of therapeutic sera

for all types of pneumonia for which serum is recognized as effective

The Department will be enabled to undertake a more comprehensive general pneumonia control program with particular emphasis on the dissemination of information to physicians and on general education of the lay public. It is proposed also to undertake special studies of the epidemiology of pneumonia in the hope of arriving at more adequate control measures

A series of feature articles on pneumonia and its control written for the *New York Evening Post* by Karl Bostrom had a large part in creating the public sentiment which supported this measure. It also had the active support of the medical profession both in New York City and upstate.—*Health News*, April 26, 1937

DR DANIEL CHARLES O'NEIL, Chief of Staff of the Endicott Johnson medical centers and hospitals, died on April 22 at the Wilson Memorial Hospital in Johnson City

Cayuga County

THE REGULAR MONTHLY meeting of the woman's auxiliary of the Cayuga County Medical Society was held on April 15 at the City Hospital in Auburn. Miss Florence Webster gave a travel talk on her trip around the world

Chautauqua County

THE JAMESTOWN MEDICAL society was addressed by Dr Douglas P Arnold, attending physician of the Buffalo Children's hospital, whose subject was "The Etiology, Diagnosis and Treatment of Birth Injuries of the Head" at the monthly meeting on

Apr 29. Dr George M Shearer presided and Dr Fitzgerald H Clark led in the discussion

Columbia County

THE SEMI-ANNUAL MEETING of the Columbia County Medical Society was held at Copake Falls, May 11. A business session was followed by luncheon and a scientific meeting. "Splenomegaly," was the topic, by Dr John J Clemer, Jr, of Albany. Dr R E Bowerhan, of Copake, gave the vice president's address

At the meeting on May 27, Dr Ellery Allen of the University spoke on "Anemia." The discussion was led by Dr C H Culver. A smorgasbord was served after the meeting

Cortland County

THERE STILL IS TOO MUCH delay on the part of patients in reporting to their physicians symptoms of cancer, Dr Donald Guthrie, chief surgeon of the Robert Packard Hospital at Sayre, Pa, told members of the Cortland County Medical Society and guests assembled on April 16

Speaking before a large audience including local and visiting physicians, Dr Guthrie said that considerable delay existed because of a false belief that the disease is incurable, a feeling of disgrace, and other causes. Because of publicity given to cancer there is a gradual trend on the part of

these cases in visiting a physician earlier than in the past, the speaker pointed out

He advised physicians not to delay the operation to await laboratory diagnosis and explained the procedure in operating on cancer

Genesee County

DR. HERMAN E PEARSE of Rochester addressed the Genesee County Medical Society at a meeting in the Batavia Club on April 29

Kings County

DR. TSUNG-CHI YU, consul general at New York for the Republic of China, was the speaker and guest of honor at the second annual luncheon of the Woman's Auxiliary to the Medical Society of the County of Kings on May 11

Dr Yu spoke on the part played by the women of China in planting and cultivation of the seeds of democracy

THE REGULAR MEETING of the Woman's Auxiliary to the Medical Society of the County of Kings, Mrs Edwin A Griffin, president, was held on April 13 at 1313 Bedford Ave. The guest speaker was Dr Silverman, whose subject was "Social Hygiene."

The annual luncheon was held on May 11 at the Hotel Astor, Manhattan

THE RIDGEBORO MEDICAL SOCIETY held its monthly meeting on April 15 at the Kings County Lighting Company Building. Dr Harry Meyersburg spoke on "Treatment of Nasal Allergy"

THE BROOKLYN THORACIC SOCIETY, having completed the first year of its organization most satisfactorily, has re-elected all of its present officers. They are President, Dr Foster Murray, vice-president, Dr John E. Jennings, treasurer, Dr Harry Meyersburg, secretary, Dr Alexander L. Louria.

The last meeting of the Society was held April 16, at which Dr Edward D Churchill, Visiting Surgeon of the Massachusetts General Hospital of Boston, delivered a discourse on Lobectomy and Pneumonec-tomy with a special reference to Primary Carcinoma of the Lung—Reported by Foster Murray, M.D., President

CONGRESSMAN EUGENE J. KEOGH of the 9th District has received three letters from an unnamed Brooklyn physician, who threatens, unless Congress does something "about the Roosevelt dictatorship," to sell his

house and other property and settle in some foreign land. He says he is forced to that decision by the Roosevelt court program and the epidemic of sit-down strikes. The doctor offers the first chance on his house to the Congressman

Montgomery County

SERUM TREATMENT FOR PNEUMONIA was the subject of two addresses before the Medical Society of the County of Montgomery on April 14 at St. Mary's Hospital in Amsterdam. The speakers were Dr H. W. Lyall, assistant director of the State Division of Laboratories and Research, and Dr Edward S. Rogers, director of the Bureau of Pneumonia Control in the Division of Communicable Diseases

Nassau County

A PAPER ON "Surgical Complications of Influenza" was presented by Dr John Edward Jennings at a scientific session of the Nassau Medical Society in the Bar Association clubhouse, Mineola, on April 27. In introducing Dr Jennings, Dr Henry B. Smith, president of the association, said the speaker "has had surgical experience which can be equalled by few men in the large centers of this country." A dinner to Dr Jennings was given in the club house. Dr Jennings is senior surgeon at Brooklyn Hospital, St. Peter's Hospital, St. John's and the Cancer Institute. He is President of the Brooklyn Chapter of the American College of Surgeons and representative from Long Island of the Boards of Regents of the American College of Surgeons

New York County

DR. KOVACS, CHAIRMAN OF THE Special Committee on Physical Therapy of the Medical Society of the County of New York, reported recently that at the request of the Executive Secretary of the Medical Information Bureau a letter of protest was sent to a certain station in regard to a commercial broadcast or home diathermy. Other complaints along these lines were referred to the sub-committee on radio advertising for further study and investigation. The chairman also reported an interview with an investigator of the Federal Trade Commission, furnishing data in the case of alleged fraudulent advertising to the laity by a short-wave diathermy concern

A REPORT WAS RECENTLY made to the Committee on Economics on the matter of cooperative societies which give medical

service to patients at reduced fees. The Workmen's Circle was discussed. There are about 200,000 people in the metropolitan district who belong to it. It is only supposed to take members of trade unions but many other individuals belong. The main objections to this organization are that it has a fixed fee schedule, there is no free choice of physicians, and the remuneration is below that of the Workmen's Compensation Law. The Workmen's Circle deducts from the fees collected for their administrative expenses, and the doctors are chosen by a lay committee.

The People's Medical League, formerly the Family Health Service League, was also reported upon. Essentially it is a cooperative plan between individuals and families in the small income group. There is a membership fee of a dollar a year per person. It has a Board of Directors, a lay Advisory Board, a Medical Advisory Board, and a Dental Advisory Board. Originally, the medical and dental boards were supposed to have sole discretion in medical and dental matters such as fees, etc., but after a short time this was taken out of their hands and put in the hands of a lay board. The fees are quite similar to those of the Workmen's Circle. The patient calls the office and is given a list of physicians belonging to the League whom he may call upon. He pays the doctor, who does not return any of this money to the organization. The main objections to this organization are similar to those to the Workmen's Circle.

DR GEORGE HENRY FOX, one of the first American physicians to specialize in dermatology, died on May 3 at his home, in New York City. He was ninety years old, a former president of the Medical Society of the County of New York and of the New York State Medical Society, and the only survivor of the founding members of the American Dermatological Association.

THE GEORGE M KOBER MEDAL, one of the most prized recognitions in the medical profession, was awarded on May 5 to Dr William H Park, director of laboratories of the New York City Department of Health.

The gold medal is awarded annually by the Association of American Physicians to the member who has gained international recognition through his contributions to medicine. Membership in the association, which held its fifty-second annual convention in Atlantic City, is limited to 200.

Dr Park was cited for his research work in infectious diseases and immunity to

them, particularly in regard to diphtheria. His laboratory is recognized as one of the finest for the study of these diseases in the United States.

Dr Rufus Cole, director of hospitals of the Rockefeller Institute, New York, was chosen by the council of the association to be the recipient of the medal next year. The award fund was endowed by the late Dr Kober of Washington, international leader in public health work.

Oneida County

STATISTICS JUST ANNOUNCED show a gain in births and a drop in deaths in Oneida County for 1936 as compared with 1935.

ABOUT ONE HUNDRED DOCTORS, dentists and their wives were carried in fancy to the jungles of Africa during a lecture by Wynant D Hubbard at the Yahnundasis Golf Club on April 15.

Sponsored by the Utica Academy of Medicine and the Utica Dental Society, the dinner meeting provided a series of illustrated adventures.

Mr Hubbard, who went to Rhodesia as a mining engineer, remained there about eleven years to capture wild animals. He said his success was due to taking the animals while they were young and before they had acquired the bad habits of their ancestors. He harbored elephants, lions, buffaloes and many other animals.

Onondaga County

THE WOMEN'S AUXILIARY of the Onondaga County Medical Society met on May 4 at the home of Mrs J Winthrop Pennock, Syracuse. Dr O D Chapman spoke on food poisoning. Dr Irving A Oberlander, baritone, sang.

ALL BUSINESS WAS SUSPENDED on April 13 in the village of Pompey while hundreds of the population attended the funeral of Dr Frederick Austin Hunt, "physician, political leader and friend." As one villager summed up this old-time family doctor's services: "Only last week, two days before he died, Doc Hunt was called out to set a rib. There wasn't anything he didn't do for us, even pulling teeth. He went out on emergency cases even after he was county clerk. Why in the days before he was supervisor it was unheard of for a Pompey woman to go to a hospital to have a baby. Doc Hunt brought them all into the world."

DR ELIZABETH M GARDINER, director of the Division of Maternity, Infancy and

Child Hygiene of the New York State Department of Health, addressed the Women's Auxiliary to the Onondaga County Medical Society on April 6 in the nurses' recreation room of Syracuse Memorial Hospital. Auxiliary members of the Cayuga and Madison County Medical Societies were guests of the Onondaga group for the meeting. Mrs H Walden Retan, new president, was in charge. Mrs Retan, formerly vice president of the Auxiliary, succeeded Mrs Francis R. Irving in the presidency when the latter resigned to take over her duties as president-elect of the New York State Auxiliary. She is engaged in organizing nine additional counties prior to the State convention.

Orange County

AFTER AN ADDRESS BY District Attorney Henry Hirschberg of Newburgh, in which he branded the present coroner system in Orange county as archaic, the Orange County Medical Society, May 13, at the Hotel Palatine in Newburgh, voted in favor of abolition of the four coroner posts and the appointment of a qualified medical examiner to take over the duties now performed by the coroners.

The District Attorney asserted that under the present system it seemed to be a fixed plan to refrain from notifying the prosecutor's office of deaths by violence until after the doctors and embalmers had done their best to destroy the evidence. He mentioned three specific cases since he took over the prosecutor's work three years ago in which valuable clues had been destroyed before his office was notified of the crime.

While the physicians favored District Attorney Hirschberg's main point of replacing coroners by a medical examiner, they differed with him on the source of the proposed new official's appointment.

Mr Hirschberg contended that the medical officer should be appointed by the District Attorney. The physicians, as their views were expressed by many of those present, thought that the appointment ought to be under Civil Service.

Physicians urged that a man who would be willing to qualify himself for the office by the study of pathology, bacteriology, criminology and other such subjects, would want a greater permanency in office than the three years term of the District Attorney. And they argued that a better man would be secured under Civil Service than by political appointment.

DR. ROBERT J HEWSON of Monroe was

appointed chairman of a committee for revision of the by-laws of the County Society.

A MEETING OF THE Woman's Auxiliary of the Orange County Medical Society was held at the home of Mrs W H Snyder, Newburgh, on April 20. There was a good attendance and several new members were elected.

Three delegates were elected to represent the Auxiliary at the State Convention at Rochester.

Oswego County

A VIGOROUS CAMPAIGN of education for the control and prevention of cancer was carried out by the Medical Society of the County of Oswego in May, with public meetings in Oswego, Fulton, and Pulaski. The speaker was Dr Charles Swan of Rochester, chairman of the state commission for the prevention of cancer.

Queens County

DR JAMES REULING, president of the Medical Society of the County of Queens, awarded silver loving cups to the eight schools showing the highest percentage of physical defects corrected during the past year in their respective schools, during child health day exhibits at the Medical Society Building on May 3.

Thousands of children attended the exhibit during the week. They were served with ice cream and chocolate drinks.

AN EXPANDED ACTIVITY program is planned for the Rockaway Medical society during the coming year to mark its fifth anniversary. Dr Louis A. Sarrow, new president, announces. Augmented meeting programs will be arranged. Dr Sarrow was named to succeed Dr Ferdinand H. Herrman, at the annual election. Other officers are Dr Milton Morris, vice president, Dr Charles W. Martin, treasurer and Dr Alfred Calvelh, secretary.

Rensselaer County

THE RENSSELAER COUNTY MEDICAL Society has started an agitation for more visible house numbers in Troy, and the Chamber of Commerce is supporting it. The doctors find the present situation unfortunate and dangerous to life. Very often, on emergency calls, they are unable to locate patients except after a long search for the house. As a few minutes sometimes mean life, it is important the doc-

tors feel that everything should be done to make house location easy. The society would like a law passed which would compel people to place four-inch high numbers in conspicuous places on the front of their homes. The numbers should be seen easily from an automobile in the middle of the road. A similar law was passed in Buffalo recently and only three months was required to put up the new numbers.

DR. JOHN J. RAINEY, of Troy addressed the Vermont State Medical Society on April 28 at Rutland, on "Practical Consideration of Nasal Accessory Sinuses."

Richmond County

DR. ALFRED H. THOMAS, sixty-two, a major in the World War, star fullback at Yale, and a prominent general practitioner on Staten Island for 37 years, died on April 15 at Staten Island Hospital, where he had been a staff surgeon.

Saratoga County

MORE THAN 800 physicians of Eastern New York and adjoining sections of Vermont and Massachusetts have been invited to the annual spring meeting of the Saratoga County Medical Society, June 3.

Results of treatment with the use of underwater methods will be the subject of the morning session. Dr. Leroy Hubbard, first medical director of the Georgia Warm Springs Spa and now connected with the large work of the Georgia Warm Springs Foundation, will discuss "Poliomyelitis—its Recognition and Treatment." Dr. John Currence of the Department of Physical Therapy of the Post-Graduate Hospital and the Lincoln Hospital, will present a paper on "Hydrotherapeutic Treatment of Arthritis and Related Conditions."

Visiting physicians will be given opportunities to inspect the buildings of the Saratoga Spa, practically all of which will be in operation at that time.

"Nephritis" is the general topic of the afternoon symposium. Dr. Paul L. Klemperer, pathologist of the Mount Sinai Hospital, New York, will discuss "Vascular Diseases of the Kidney—Pathological Aspects." Dr. Herman Mosenthal will discuss "Prevention and Treatment of Uremia," with attention to the general treatment of nephritis.

Tompkins County

ITHACA AND TOMPKINS County joined in a two-day conference on syphilis control

on May 5 and 6, with fifty-two community organizations cooperating.

Ulster County

A TWO-DAY INSTITUTE on the control of syphilis was held in Kingston on May 27 and 28, with over fifty city and county organizations participating.

Wayne County

MEMBERS OF THE Wayne County Medical Society were guests of Dr. C. L. Vaux at the State School for their regular April meeting, April 6. Following dinner, the program included presentation of cases by Dr. H. G. Hubbell, clinical director of the School. Dr. John Hoeffler reported on the first 1,000 admissions to the new boy's school.

Westchester County

THE YONKERS ACADEMY OF Medicine on April 21 "tossed the vexing immunization problem back into the lap of the Department of Health," as a Yonkers paper puts it.

By an overwhelming vote, the physicians, meeting at the Hudson River Country Club, favored establishment of a free clinic at City Hall to take care of anti-diphtheria immunization service.

The city discontinued its free clinic in 1933, giving the work over to private physicians, who were paid on a fee basis for caring for indigent cases.

The academy attributed failure of the system in effect since that time to neglect of parents in bringing their children to the doctors for treatment. The consensus was that free clinics would eliminate that obstacle to one hundred per cent immunization.

The action of the academy follows a storm of protest from parent organizations of the city, deploring the apparent failure of the current system, and a promise by Dr. John A. Farella, Acting Health Commissioner, that he would reestablish free city clinics if the physicians want them.

The first clinic was held on April 24 at the City Hall, to be repeated every Saturday.

The restoration of the clinics writes finis to a three and one-half year experiment in "private administration of public health" inaugurated by the late Dr. Clarence W. Buckmaster, Health Commissioner, at the behest of the Academy of Medicine. Other recommendations of an Academy committee—that other phases of public health work be transferred to the private physicians—were rejected shortly after that.

Hospital News

How Albany Hospital Does It

TO CUT ITS LOSS by bad debts from four or six per cent down to around one per cent of earnings is a surgical operation that many a hospital would delight to perform. Albany Hospital did it, and how it was done is told by E. W. Jones and R. R. Potter in *The Modern Hospital* for February. One per cent of loss, as they remark, "compares favorably with merchandising and industrial experience."

In the first place, every patient, on entering the Albany hospital, is rated by the credit manager, on the basis of all available information, as "O K. with no reservation," "O K. Weekly," "O K. Weekly with one special nurse," "O K. Weekly except special nurses," "Weekly in advance," or "Strictly advance."

All patients are billed weekly, some in advance, and others on an accrued basis, depending on the classification of the account. These billings are made by the cashier and are cleared through the credit manager before they are mailed.

"The credit manager," we are told further, "follows these accounts closely, the procedure being that three days are allowed for the bill to reach its destination, and a check to be written and sent to us. If a remittance is not received at the end of the third day after the bill is mailed, the account is carefully scrutinized, and if it appears advisable, a letter is sent requesting that the bill be honored. It is again checked at the end of three more days and if no reply to the bill or follow-up letter has been received, we again determine what the next move should be.

"If a discharged patient for some reason is not in a position to pay his account in full, his financial problems are discussed with him to determine to our satisfaction, as well as his, what method should be adopted in liquidating the account at some future time, and we accept a note for the unpaid balance, which note is payable according to terms agreed upon. We attempt never to accept a note on which payment in full or in part is not due within 60 days.

It is a common experience that the longer an account runs, the harder it is to collect.

"The majority of those from whom we must accept notes are working at low salaries and can afford to pay only a small portion of their periodic income on such an account. For this reason, we usually attempt to have the payer agree to pay a certain amount of his periodic income on the account until it is entirely liquidated. In this way the account is always a current one from the date of the last payment.

"Following is a detail of the general procedure used in following our accounts receivable.

"Accounts Owed by Individuals

"If payment is not received at the time, a bill is either given to the patient or forwarded to the guarantor immediately after the patient is discharged, or special services such as X-ray, special laboratory, electrocardiograph, are rendered. The account is flagged for one week from that date, unless a note is received.

"When notes are accepted, the account is flagged for three days before the due date and a notice reminding the individual of his obligation is sent to reach him one day before the note is due.

"If payment is not made when due on a note or within one week from rendition of a bill when no note has been obtained, a second statement is mailed and again the account is flagged for one week from that date. A follow-up letter accompanies the statement.

"If after another week we still have received no payment and have not heard any word from the patient, we forward a letter reminding him of the indebtedness and requesting payment. The account is again set up in file for one week from that date.

"With no action at the end of the third week, we mail another letter requesting that the patient either remit, or state on reverse side the reason why payment cannot or should not be made. Once more the account is flagged for one week hence.

"If we receive no word by the end of the fourth week, we write insisting that the account be given immediate attention, and the account is again set up in file for the following week.

"By the end of the fifth week, it is obvious that the debtor does not intend to reply to our stereotyped letters and we therefore either forward him a specially dictated letter or refer the account to a personal contact man if the payer resides locally, or to the collecting agency which handles this work for us on out of town accounts.

"We keep a close check on local accounts

through the contact man and if he does not obtain satisfactory results within a reasonable time, we refer them to the collection agency.

"All accounts which have been referred to the collection agency are reviewed twice a year. All accounts which for one reason or another appear to be uncollectable and those which we may possibly have been able to determine to be so before they are referred to the agency, are tabulated on a report which is referred to our governing body with recommendations that they be written off twice yearly."

Importance of a Good Medical Library

THE SOUL OF AN INSTITUTION resides in its library, said Harvey Cushing some ten years ago at the opening of the new Cleveland Medical Library building, and he went so far as to aver that one gauge of the quality of a hospital is the condition of its library. That is not to say, of course, that the hospital's books are more important than its other equipment, but merely that a good hospital will have a good library and a poor hospital will have a poor one.

The importance of the medical library is evident when the Council on Medical Education and Hospitals of the A.M.A. specifies in the "Essentials in a Hospital Approved for Training Interns" that there must be a working medical library with "a useful selection of late editions of standard text and reference books and current files of not less than ten of the better medical journals." It is not enough, either, to have the privilege of using a medical library, however good, located in some other institution. It "should be inside the hospital building, and be located where it is readily accessible to the interns and staff members."

Serious limitations hamper a medical staff which tries to work with little or no reference to books and journals, truly remarked Dr. Vincent at the fiftieth anniversary of the Boston Medical Library in 1926. They are liable to mistakes, waste, duplication of effort, they "become victims of empiricism and routine, imagination and initiative lack stimulus, enthusiasm and energy decline, minds grow sterile that under the quickening influence of the recorded experience of others might have been fruitful."

It is so easy, too, to organize a serviceable library if the medical and administrative staffs really go to it with energy and determination, for quality is more important than quantity, and a workable selection of choice medical periodicals, standard texts, and reference books is within reach of almost every hospital. The first step is to appoint a library committee, and right here a wrong choice may cripple the entire enterprise. "Many library committees are such in name only," says the *Journal of the A.M.A.*, and "care should be exercised in order to assure the inclusion of such doctors as would take an active interest."

As little as \$300 a year will establish and maintain a hospital medical library, in the opinion of the A.M.A. Council on Medical Education and Hospitals. When we consider how many times \$300 are spent on other things (necessary, of course) around a hospital, it would seem that the money could also be found for this purpose. If not, the staff members can perhaps raise it among themselves, or friends or auxiliaries may contribute it if they realize the need.

When the library is assured, the next question is, where to put it. It will be only natural for the administrative authorities to think first of some disused lumber room on the top floor, for our busy hospitals are now using every inch of space, and wishing for more. This is where the alert library committee gets busy and insists on a proper location. "The hospital medical library," declares the Council, "should occupy a prominent location, preferably in the hospital building. The actual location of the room will affect

directly the amount of usage. If it is placed in an obscure corner of a floor that is used very little as compared with other floors, it will naturally not be visited often. The location should be chosen with a view to attractiveness, convenience and comfort to those who will use the library. It is often preferable to have it on the administrative floor or in close proximity to the doctors' room. The room should be sufficiently large to house the books along with the necessary furnishings, and to permit its comfortable use for reading, discussion and conversation. The very atmosphere of the room will have much to do with the extent to which the library will be used."

Some helpful advice is also given by the Council on the choice of books. In the *Journal A.M.A.* of March 27 it gives a list of suggested works and periodicals, and observes

In establishing the library, it is well to purchase only one or two comprehensive textbooks on each subject. Only recent books should be chosen, with the exception of such standard

works as are recognized as classics in their respective lines, and which do not grow obsolete with age. The literature on therapy and diagnosis, for example, is changing so rapidly as to warrant the use of the most recent books. In the field of the more fully developed sciences, such as anatomy and histology, literature is more stabilized and longer lived. More recent editions of the standard textbooks should be added from time to time thus keeping the library up to date with regard to new methods of diagnosis and treatment that have been digested and tested. After a good foundation has been formed, the balance of the apportioned funds may be expended in purchasing varied references that are known to be of particular value. The library should not be allowed to become a depository for antiques, and out of date books should be removed or discarded.

The usefulness and efficiency of the hospital medical library depend not only on a good selection of medical books but also on a well chosen group of periodicals. Limited library funds are often more usefully expended for periodicals than for texts and references. When ample funds are provided there is no great difficulty experienced in the matter of choice.

Human Rights and Hospital "Sit Downs"

THE CONVICTION IN SPECIAL SESSIONS of seventeen persons in connection with a sit-down strike in the Jewish Hospital is significant and should be salutary, remarks the *Brooklyn Eagle*. It is absolutely necessary, if workers are to continue to improve their lot through organization, for certain distinctions to be made between various abstract rights and definite acts. If no distinctions are to be made between sit-down strikes in hospitals and ordinary labor disputes, then some special arrangement must be made, we are told, to assure protection to helpless people who are the potential sufferers from the lawlessness of such sit-down strikes.

The defense in the Jewish Hospital strike was that no real harm came to patients. That was not the point involved. Serious harm might have resulted from the acts of the defendants. It is possible to drive down the wrong side of the street without hurting any one but it is a violation of traffic regulations, and the fact that no one suffers would not excuse the driver.

Hospital workers deserve something more than ordinary consideration from hospital

managements and the public. Their duties are arduous and their compensation is declared by the *Eagle* to be shamefully inadequate. And they have a right to organize and to strike, if they are so inclined, to impress their employers with their demands. But a sit-down strike in a hospital is another matter. Such action cannot be undertaken without jeopardizing the welfare, if not the lives, of patients.

One of the most confusing aspects of the present labor situation is that it is so difficult to make distinctions. We are far behind some other countries in labor legislation. One reason for this is that we have a dual form of government. Another is that we were so long a predominantly agricultural country and clung so tenaciously to the old ideas of rugged individualism that no serious efforts were made to deal with industrial problems.

Still another reason is that politicians have lacked the courage and the capacity to do anything more than try to please organized groups. Meantime labor has been ruthlessly exploited and has had to fight every step of the way toward betterment.

This has produced a not unjustified conviction on the part of many workers that the only way to get anything is to fight for it.

The current strike contagion represents long years during which workers have suffered from genuine abuses. In the last few years they have made startling gains in many fields, and it is only natural that they should want to go on. But it is necessary to make distinctions. There are certain essential services, such as hospitals,

which cannot be suspended without danger to others.

The Jewish Hospital strikers were convicted under an old law going back to 1881, but the principle invoked is as old as law itself. The whole purpose of law is to protect society. Much has been said about sit-down strikes as affecting property rights as distinct from human rights. The hospital sit-down strike violated both property and human rights.

Improvements

THE CORNERSTONE OF THE NEW \$125,000 hospital and clinic building of the Bronx Eye and Ear Infirmary was laid on April 24. It is practically completed and will be opened soon.

THE NEW \$1,250,000, eight-story Jewish Memorial Hospital building, at Broadway and 196th St., New York City, will be dedicated during the week of June 13, it was announced at the annual meeting of the institution in the Hotel Astor.

THE HOSPITAL FOR JOINT DISEASES in New York City, has successfully completed its campaign for \$650,000 to build a new outpatient department addition.

THE JEWISH SANITARIUM and Hospital for Chronic Diseases, in Brooklyn, plans to build a \$500,000 wing for the treatment of infantile paralysis sufferers.

NASSAU HOSPITAL at Mineola, is looking to the replacement of the present buildings with "a new and modern hospital structure," says President Hoppin in his annual report.

THE MEMORIAL HOSPITAL of Greene County, at Catskill, has opened a new addition, increasing its capacity from twenty-four beds to fifty.

AN ADDITION TO Buffalo General Hospital, costing between \$125,000 and \$150,000, will be started at once, it is announced by Dr. Fraser D. Mooney, superintendent. Three stories high, the new build-

ing will have twenty patient rooms, a surgical department, and staff rooms. The surgical department, taking up the entire second floor, will be one of the most modern in the country.

THE BUFFALO EMERGENCY HOSPITAL has started the construction of a five-story addition, to cost \$158,000. The new wing will house an emergency operating room, first aid room, x-ray and physical therapy departments, pathological laboratory, a pharmacy, and a new chapel. There also will be a new central diet department and increased facilities for internes and the administration department.

THE TOWN BOARD HAS authorized the Seneca Falls Hospital Board of Managers to make preliminary plans for an addition to the present institution or for a new building. Several times state inspectors have criticized the hospital for overcrowded conditions and for lack of a department that could be given over entirely to maternity cases.

GROUND HAS BEEN BROKEN for a new hospital to be built in Olean by the Sisters of the Third Order of St. Francis. It is hoped to complete the structure by fall. It will be known as St. Francis Hospital, and will care for one hundred patients.

PEEKSKILL HOSPITAL WILL repair and re-furnish the nurses' home.

THE OPENING OF ONEIDA's new \$220,000 municipal hospital is slated for July 1.

Newsy Notes

FOR THE FIRST TIME in a generation, the Lenox Hill Hospital, in New York City, reports a balanced budget. This happy condition, says its annual report, is due to legacies left by loyal friends. The "three-cents-a-day" plan is also proving helpful.

A LARGE PROPORTION of its admissions and virtually all its emergency cases last year were automobile accident victims, declares the annual report of the Hebrew Hospital at Monticello.

VETERANS AND THEIR FAMILIES are again to be admitted to the Oneida County Hospital. Two years ago the managers barred them on the ground that they could find accommodations in institutions provided by the Federal Government. With the opening of the new annex, the hospital now has more room, and the previous action has been rescinded.

THE NINETEEN PHYSICIANS on the staffs of the Rome Hospital and the Murphy Memorial Hospital have offered to serve all hospitalized relief cases for \$3,800 a year or \$200 a year for each. Formerly this service was given without charge. The Home Relief Bureau has been notified of the offer and it is expected the Common Council will be asked for an additional appropriation to meet the added expense. The figure is a compromise as the physicians previously had stated they would serve relief cases only at regular rates. The bureau committee asked a schedule of rates and the physicians then made the \$3,800 offer.

DR. JAMES P. CROCE has been appointed Professor of Internal Medicine at the New York Polyclinic Medical School and Hos-

pital, not Professor of Urology, as stated by error in these pages on April 1.

THE NEW WYOMING COUNTY HOSPITAL at Warsaw is well under way. The foundations are completed and work on the superstructure is starting.

ARCHITECTS ARE MAKING PLANS for a new fireproof structure to replace the present frame building of the Eastern Long Island Hospital at Greenport.

A NEW GARAGE AND male dormitory will be constructed at Fordham Hospital.

BINGHAMTON HAS APPLIED for a \$850,000 PWA grant for the construction of an addition to the City Hospital.

ST JOHN'S RIVERSIDE HOSPITAL in Yonkers contemplates the erection of a new building.

THE NEW UNIT OF THE Boulevard Hospital, Astoria, housing an auditorium, laboratory, and other hospital facilities was dedicated on March 22.

SECURITIES WORTH \$315,000 have been donated by C. B. Winslow, of White Plains, to the \$1,200,000 fund being raised for the White Plains Hospital project.

PLANS HAVE BEEN FILED in White Plains, for additions to the main building of St. Agnes Hospital to add facilities that will include thirty-nine new private and semi-private rooms with fifty-one beds for patients. The estimated cost is \$100,000.

At the Helm

The following hospital officials have been chosen:

DR. CHARLES D. PARFITT, to be medical director of Loomis Sanatorium, at Loomis, Sullivan County.

EDWARD C. ROWE, reelected president of Loomis Sanatorium.

DR. STANLEY P. JONES, to be Chief of

Staff of the Eastern Long Island Hospital.

MRS. CARLTON SWEET, to be Superintendent of the Oneida Public Hospital.

DR. ARTHUR F. KRAETZER, to be Director of the Department of Medicine of the Knickerbocker Hospital.

DR. STEPHEN H. ACKERMAN, to be medical superintendent of Fordham Hospital.

Events

DR CLAUDE W MUNGER, newly appointed head of St Luke's Hospital, was guest of honor at a dinner May 11 at the Westchester Country Club, Rye. The advisory board of the Westchester County Department of Public Welfare arranged the dinner in recognition of Dr Munger's sixteen years service as director of Grasslands Hospital at Valhalla.

A GALA PRIMAVERA ENTERTAINMENT was given on May 1 at the Plaza Hotel in New York City in behalf of Columbus Hospital, under the joint auspices of the Ladies and Junior Auxiliaries of the hospital. In addition to general dancing throughout the evening there was a song program by Miss Josephine Antoine and Robert Weede of the Metropolitan Opera and dancing numbers by professionals.

THE ANNUAL DINNER DANCE of the Glens Falls Hospital Guild was held on May 1 at the Queensburg. It was "the high point in the social life of the season," say the Glens Falls papers.

THE ANNUAL FAIR OF THE Norwegian Hospital of Brooklyn was held at the Kings County Lighting Company Building on April 17-24, sponsored by the Ladies Auxiliary.

THE THIRD ANNUAL LUNCHEON of the Women's Auxiliary of the Schenectady City Hospital was held at the Hotel Van Curler on April 13, and brought out a large number of members and friends of the institution who were greeted by the retiring president, Mrs W G Acosta, and the newly elected president, Mrs John S Faber, who presided.

MORE THAN 200 PEOPLE paid tribute to Dr Albert R. Fritz and his brother, Dr Dudley Fritz, who founded the Madison Park Hospital, in Brooklyn, in 1930, at a dinner given by officers and directors of the hospital and physicians and laymen of the borough, at the Waldorf-Astoria Hotel, Manhattan, in April.

SENATOR JULIUS S BERG of New York City was the guest speaker at the twelfth anniversary banquet of the Monticello Hospital at the Flagler Hotel on April 25.

THE ADMINISTRATIVE STAFF of the Green point Hospital of Brooklyn held a reception and card party in the auditorium of the hospital on April 9.

POSTMASTER GENERAL James A. Farley was one of the guests at the Primavera Fiesta at the Hendrick Hudson Hotel in Troy on April 21 for the benefit of the Troy Hospital.

THE THIRD ANNUAL DINNER DANCE of the doctors of St Mary's Hospital in Brooklyn was given at the Hotel St. George on April 8. More than 900 guests attended.

PROCEEDS OF THE DANCE for the benefit of the Medina Memorial Hospital on April 2 approximated \$1,000. Over 800 were present.

THE 12TH ANNUAL BALL of the Nurses' Alumnae Association of the Greenwich Hospital was held at the Masonic Temple in Port Chester on April 3. The proceeds went to the emergency fund.

DR. PHILIP OGINZ, retiring president of the medical board of Beth-El Hospital, was the guest of honor of more than 200 Brooklyn physicians at a dinner given him by the medical board and staff of the hospital on Mar 17 in the Brooklyn Jewish Center.

THE LENOX HILL HOSPITAL, New York City, in 1936, for the first time in a generation, reported a balanced budget and was not obliged to draw on capital to meet a net deficit, it is stated in the annual report. The improvement in finances is ascribed to increased use of hospital facilities, especially in the private and semi-private departments, larger contributions from the United Hospital Fund and supporters, and the adoption of the Associated Hospital Service three cents a day plan.

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Liability of Infant for Medical Services

A question of interest to the members of the medical profession is that presented where a physician attempts to collect a fee from a patient he has treated who is under legal age. A case recently decided in one of the Southern States reaches what seems to be a fair result where the defense of infancy was asserted in answer to an action by a physician who had treated a small boy.

The action originated in a court of limited jurisdiction and was carried through an intermediate court and finally was decided upon appeal in the highest court in the State. The case was one in which there was no dispute as to the facts which will be set forth in summary.

The plaintiff, B, was a duly licensed physician who brought suit for a fee of slightly less than \$200 against T.G. an infant. Named as a codefendant in the action was the W. Bank & Trust Company, the duly appointed guardian of T.G. The child resided with and was generally supported by R.G. his father. Some years before, the minor had been seriously injured when struck by an automobile owned by one C. He was taken to a hospital where Dr. B. treated him for a long period of time. The professional services rendered were of at least the fair and reasonable value of the amount demanded. The father of the boy had frequently visited him at the hospital and made no objection to the treatment the patient was receiving, but there was no express contract of hire made between Dr. B. and the father or anyone else as to who would pay for the medical care rendered. Later, payment was demanded from the father and he refused to pay.

An action was brought on behalf of the infant against C, the automobile owner, which resulted in a judgment of \$3,000 being paid, and deposited with the bank as guardian. An action against C by the father, resulted in a judgment of \$900 which was based upon a complaint covering hospital and medical expenses, and loss of services.

The question presented to the Appellate Court was well summarized in the opinion as follows:

Is an infant living with his father liable for medical services where such services were uncontradicted but were necessary in an emergency and the infant recovers damages for the injuries which made the services necessary, although the father also recovers for his own expenses (including hospital and medical) and damages?

The Court in affirming the judgment in favor of the physician answered its own question in the affirmative, and said in the course of the opinion:

It goes without saying that the father was liable to plaintiff, the physician, for the services rendered to his infant son.

We think, under the facts and circumstances of this case that the infant is also liable. The defendants say in their brief "In good conscience and equity it ought to have been collected out of the father when he recovered his judgment in a substantial amount for the very obligation." We think this should have been done and the father liable to the infant, but from the record, it may be he is insolvent. T.G. when injured, for which recovery was had, was about seven or eight years of age. He was "seriously injured suffering a broken leg and other injuries." He was taken to a hospital and there treated by the plaintiff, Dr. B., who rendered to him certain medical and surgical services over a long period of time. It is admitted that the charges for the services rendered by plaintiff were fair and reasonable.

The Court in the opinion quoted from an earlier authority as follows:

A case in which considerations of humanity control and enable one who has rendered services without request to recover therefor, is found where medical or surgical attention is rendered to one who is injured or taken ill so that he is unconscious and unable either to request or forbid the rendition of such services. In cases of this sort, the courts are confronted with the alternative of requiring the injured person to pay reasonable compensation for services rendered to him, or of saying that all who render services do so as a matter of charity or in reliance upon the generosity of the person for whom such services are rendered. While there is little authority upon this question, from the nature of the case it is held that the interest of the person who is injured requires the law to impose a liability upon him for reasonable compensation for such medical and surgical services.

* *Bitting v. Goss*, 166 S. E. 302

The decision referred to is considerably more liberal than two earlier decisions handed down by the Appellate Term in New York State in similar situations* The general New York rule was stated as follows in the *Potter* case

In order to fasten liability upon the defendant (infant) personally, the plaintiff (physician) was required to establish affirmatively that the person charged with the duty of maintaining and protecting the infant, at the time the services were rendered, was either unwilling or unable to discharge his obligation

In the *Stetson* case the Court said

In order to fasten any liability upon the defendant for said alleged services rendered to him in his infancy it was absolutely necessary for the plaintiff to prove, in the absence of any ratification by the infant when he became of age, not only that the services so rendered were necessities furnished to the infant, but that the father was not financially able to discharge the obligation for such services, or failed to discharge his duty in furnishing medical services, or that he was unwilling to furnish such services, or would not pay for them

Alleged Malpractice in Operation Upon Knee

A man who had been receiving medical care under the Workmen's Compensation Law for about six months with respect to an injured knee was referred to a physician specializing in orthopedic surgery Previous attempts at treatment had been unsuccessful and he had not been able to return to work up to that time The doctor examined him and concluded that the patient's injury required operation He had the patient hospitalized and under general anaesthesia made an incision over the left knee for the purpose of removing a torn meniscus The surgeon also removed certain hypertrophied fat pads In the course of the operation, he found the synovial membrane and the anterior crucial ligament inflamed A plaster cast was applied which was allowed to remain on the leg for about two weeks At the end of that time, the patient left the hospital

The wound healed in a reasonable time but the patient seemed unwilling to make any attempts to move his leg The patient returned to the doctor's office for nearly a year following the operation periodically for the purpose of receiving baking and massage At the end of that time, the patient had no swelling, tenderness, or limitation of motion, but when he attempted to walk,

he still had a marked limp From that time on, various doctors attended him and it was found that the patient developed very unusual nervous symptoms although it was not possible definitely to attribute these symptoms to malingering

A malpractice action was instituted against the orthopedic surgeon charging him with negligence in his care of the patient and charging that as a result the plaintiff sustained permanent stiffness, shortening and loss of the use of his left leg which rendered him a permanent cripple Subsequent to the conclusion of the treatment of the plaintiff by the defendant, he received a substantial award of Workmen's Compensation covering his injuries The said fact was availed of on behalf of the doctor in defense of his action both in mitigation of damages and upon the ground that the plaintiff had elected to pursue his remedy under Workmen's Compensation rather than to proceed against the doctor in the malpractice action

The case came on for trial before a judge and jury and at the end of a three day trial, after the testimony on both sides had been taken, the court directed a verdict in favor of the defendant thereby exonerating him of the charges of malpractice which had been made against him

Glass in Hand

A young woman who was employed as janitress of a tenement house, consulted a physician specializing in surgery with respect to an injury to her hand She gave him a history of falling and cutting her hand on the broken glass of a window a week before The doctor found a partly healed laceration about one inch and a half long upon the back of her left hand between the first and second metacarpal bones He carefully dressed the wound on that day and renewed the dressings on four later occasions during the next week when she called at his office He heard nothing from the woman for somewhat over a year when she returned to him complaining of pain in the hand He then had an x-ray picture taken which showed a shadow near the site of the old wound The doctor opened the old incision and found a small sliver of glass about three-fourths of an inch long which he removed He continued to care for the patient until the wound again healed

Within two years after the last series of treatments, but more than two years after the first, the patient instituted a malpractice action against the doctor charging him with negligence in having failed to re-

* *Potter v. Thomas* 164 N. Y. S. 923, *Stetson v. Thomas* 164 N. Y. S. 713

MEDICOLEGAL

Number 111

move the glass when he first treated her. In addition to the defense that the doctor had not been guilty of malpractice in treating the case, a special defense was interposed in the case that the cause of action was barred by the two year Statute of Limitations.

Before the case was tried, a physical examination showed that the plaintiff's use of the injured hand was considerably restricted. Said examination, however, indicated that the disability was probably due to a hysterical neurosis.

The case came on for trial before a judge and jury, and at the conclusion of the testimony of the plaintiff and her witnesses, the complaint was dismissed thereby terminating the action in favor of the doctor defendant.

Death of Child Owing to Ruptured Appendix

A general practitioner was called to attend a three year old child. Upon examination he found a respiratory infection with rales in the lungs, particularly pronounced on the right side. He found that the child had a high temperature and pulse. He prescribed for the condition and kept the child under careful observation for two days when he observed rigidity and tenderness of the abdomen. He immediately called in a child specialist to confirm his tentative diagnosis of appendicitis. The pediatrician decided that the child should be immediately taken to a hospital for observation. At the hospital it was determined that the case was inoperable and the next day the child died. An autopsy revealed that the child had died from pneumonia and general peritonitis caused by a ruptured gangrenous appendix. A malpractice action was instituted against the general practitioner charging

him with having negligently caused the death of the child by failing promptly to diagnose his true condition. The case came on for trial before the Court and a jury and the plaintiff failed to establish that the doctor, in his care of the child, in any way departed from proper and approved medical practice. The Court, therefore, dismissed the complaint at the conclusion of the testimony on behalf of the plaintiff.

Diathermic Burn

A physician engaged in general surgery, was asked by an insurance company to make an examination of a patient who was receiving treatment under the Workmen's Compensation Law, and to advise with respect to what further treatments should be rendered him. The doctor, upon examination, learned that the man had injured his finger some time before and that there was a well-healed scar on the surface of the distal end of the first finger of the right hand. The doctor found stiffness at the joint and recommended that he should receive baking and massage. The doctor rendered no treatment but directed him to obtain the needed baking and massage from a physiotherapist in the employ of the insurance company. It appeared that on the same day a baking treatment was rendered by the physiotherapist and that the man received a burn.

An action was brought against the doctor, the physiotherapist, and the insurance company charging each of them with responsibility for the burn. However, when the case was about to be reached for trial, counsel for the defendant physician succeeded in persuading the plaintiff's attorney that there was no legitimate basis for a cause of action against the doctor and this action was discontinued as to him.

DREAMS

Preventive medicine dreams of a time when there shall be enough for all, and every man shall bear his share of labor in accordance with his ability, and every man shall possess sufficient for the needs of his body and the demands of health. These things he shall have as a matter of justice and not of charity.

Preventive medicine dreams of a time when there shall be no unnecessary suffering and no premature deaths, when the welfare of the people shall be our highest concern, when humanity and mercy shall

replace greed and selfishness, and it dreams that all these things will be accomplished through the wisdom of man.

Preventive medicine dreams of these things, not with the hope that we, individually, may participate in them, but with the joy that we may aid in their coming to those who shall live after us.

When young men have vision, the dreams of old men come true—Milton J. Rosenau, M.D., in the *Bulletin*, Kentucky State Department of Health.

The decision referred to is considerably more liberal than two earlier decisions handed down by the Appellate Term in New York State in similar situations*. The general New York rule was stated as follows in the *Potter* case

In order to fasten liability upon the defendant (infant) personally, the plaintiff (physician) was required to establish affirmatively that the person charged with the duty of maintaining and protecting the infant, at the time the services were rendered, was either unwilling or unable to discharge his obligation

In the *Stetson* case the Court said

In order to fasten any liability upon the defendant for said alleged services rendered to him in his infancy it was absolutely necessary for the plaintiff to prove, in the absence of any ratification by the infant when he became of age, not only that the services so rendered were necessities furnished to the infant, but that the father was not financially able to discharge the obligation for such services, or failed to discharge his duty in furnishing medical services, or that he was unwilling to furnish such services, or would not pay for them.

Alleged Malpractice in Operation Upon Knee

A man who had been receiving medical care under the Workmen's Compensation Law for about six months with respect to an injured knee was referred to a physician specializing in orthopedic surgery. Previous attempts at treatment had been unsuccessful and he had not been able to return to work up to that time. The doctor examined him and concluded that the patient's injury required operation. He had the patient hospitalized and under general anaesthesia made an incision over the left knee for the purpose of removing a torn meniscus. The surgeon also removed certain hypertrophied fat pads. In the course of the operation, he found the synovial membrane and the anterior crucial ligament inflamed. A plaster cast was applied which was allowed to remain on the leg for about two weeks. At the end of that time, the patient left the hospital.

The wound healed in a reasonable time but the patient seemed unwilling to make any attempts to move his leg. The patient returned to the doctor's office for nearly a year following the operation periodically for the purpose of receiving baking and massage. At the end of that time, the patient had no swelling, tenderness, or limitation of motion, but when he attempted to walk,

he still had a marked limp. From that time on, various doctors attended him and it was found that the patient developed very unusual nervous symptoms although it was not possible definitely to attribute these symptoms to malingering.

A malpractice action was instituted against the orthopedic surgeon charging him with negligence in his care of the patient and charging that as a result the plaintiff sustained permanent stiffness, shortening and loss of the use of his left leg which rendered him a permanent cripple. Subsequent to the conclusion of the treatment of the plaintiff by the defendant, he received a substantial award of Workmen's Compensation covering his injuries. The said fact was availed of on behalf of the doctor in defense of his action both in mitigation of damages and upon the ground that the plaintiff had elected to pursue his remedy under Workmen's Compensation rather than to proceed against the doctor in the malpractice action.

The case came on for trial before a judge and jury and at the end of a three day trial, after the testimony on both sides had been taken, the court directed a verdict in favor of the defendant thereby exonerating him of the charges of malpractice which had been made against him.

Glass in Hand

A young woman who was employed as janitress of a tenement house, consulted a physician specializing in surgery with respect to an injury to her hand. She gave him a history of falling and cutting her hand on the broken glass of a window a week before. The doctor found a partly healed laceration about one inch and a half long upon the back of her left hand between the first and second metacarpal bones. He carefully dressed the wound on that day and renewed the dressings on four later occasions during the next week when she called at his office. He heard nothing from the woman for somewhat over a year when she returned to him complaining of pain in the hand. He then had an x-ray picture taken which showed a shadow near the site of the old wound. The doctor opened the old incision and found a small sliver of glass about three-fourths of an inch long which he removed. He continued to care for the patient until the wound again healed.

Within two years after the last series of treatments, but more than two years after the first, the patient instituted a malpractice action against the doctor charging him with negligence in having failed to re-

for these cycles. He was hard to handle. Once he refused to go to the dental clinic and tore his shirt." Reluctance to go to the dentist may perhaps seem perfectly normal, though the streets around dental offices are not commonly littered with torn shirts.

An Exciting Discovery

Tommy improved under treatment, but "the one thing that did not change was the peculiar fluctuation in his behavior from day to day. In school about two days out of every week he was so confused that trying to teach him anything at these times was profitless." What was there different in Tommy on those two difficult days? That was the job given to the new machine, and it responded with an amazing report. In Dr. Solomon's words:

Now, the strange and exciting discovery that this instrument permitted us to make was this. When we took brain wave records on Tommy, who was not suspected of having epilepsy, we found the same "seizure waves" that epileptics have. What is more, on the days when Tommy did poorly in school and seemed especially bad-tempered, his brain record was full of "seizure waves," while on good days when he was well behaved, his brain record was perfectly normal! Here, then, was the explanation for Tommy's peculiar behavior. We had come upon a new and unsuspected cause for misbehavior. It had previously been recognized that some epileptic individuals behave badly after their attacks. In fact, many crimes, even murders, have been committed under these circumstances. But that a child who was not regarded as an epileptic could have the same brain disturbances and the same type of behavior was something not considered before.

The implications here are extraordinary—that we have "come upon a new and unsuspected cause for misbehavior," a disturbed brain-state present in non-epileptics as well as epileptics revealed by "seizure waves."

Can We Calm the Waves?

Can this state be remedied? Can we pour oil on the troubled waters and still the waves that beat on poor, battered brains like little Tommy's and threaten to drive them into criminality? That question is engaging the attention of scientists who are using the electro-encephalograph to study

epilepsy. One of these is Dr. William G. Lennox, of the Department of Neurology of the Harvard Medical School, who told of some of his findings at the annual meeting of the American Psychiatric Association in Pittsburg in May. A milestone in the study of this disease, he said, is the demonstration that an epileptic seizure is a disturbance in the normal rhythm of the electrical activity of the brain, for this "permits concentration of attention on those elements which have to do with the brain's electrical discharge."

LEGEND FOR FIGURE

Tommy's brain waves. A. On a "bad" day (see text). B. On a good day. Lead 1 in both records was taken from an indifferent ear electrode to the vertex of the head, lead 2 simultaneously from the same indifferent to an occipital electrode. For technique, see Jasper, H. H. and Andrews, H. L., *Jour. Gen. Psychol.*, 1936, 14: 98-126.

The time line at the top of each record represents 1/20 seconds. The calibration lines under the letters 'A' and 'B' represent the excursion produced by a signal of 200 microvolts.

Record B shows normal "alpha" waves. Record A shows large 3 a second "seizure" waves.

Several factors have been found to play a part in it, he reports, according to an account in the *New York Times*. These include the strength of electrolytes (body fluids carrying electrical current), the relative amounts of oxygen and of sugar, the acid-alkaline balance of the brain cells and the permeability of the cell membranes.

"The fact that various alterations in body chemistry, such, for example as simply increasing the carbon dioxide concentration of the respired air, suppresses the abnormal electrical rhythm of epilepsy, indicates the possibility of influencing cell chemistry by chemical means," he says.

Evidence is accumulating, he adds, that epilepsy is due to a specific abnormality in neurones (nerve cells) of epileptics, but the chemical procedures which suppress the abnormal electrical rhythm have not yet revealed this specific abnormality. For ex-

Why We Misbehave like Inhuman Beings

WHEN THE RADIO SQUEALS AND squawks, we know that some wrong electrical impulse has got into it and twisted its sweet harmonies into jarring discords. A little tinkering by the repair man sets it right again. Simple enough. But now a new instrument, called the electro-encephalograph, suggests that our brains are very like radio receiving sets, an idea which conjures up alluring possibilities, and some others, which are not so much so. The radio at its best is a thing of infinite delight, but at its worst is an instrument to make the medieval torturer smile. In other words, it is strangely like our high, low, strong, weak, angelic, satanic human personalities.

The revelations of the electro-encephalograph were presented a few weeks ago in Memphis, before the Federation of American Societies for Experimental Biology, by Prof. Hallowell Davis, of the Harvard Medical School. As reported by William L. Laurence in the *New York Times*, Prof. Davis drew "outlines of a picture of life in which the activities of mind and matter constitute a super-radio, with the quintillions of living cells sending out their individual waves to be tuned in by quadrillions of receiving sets in the brain." The brain, according to this picture, which is still far from complete, "synchronized the infinity of rhythms into a symphonic poem, with the cortex of the brain, seat of the intelligence, as the conductor of the symphony."

We Each Play our Little Tune

Each of us, it appears, has a different brain-wave record, as shown by the electro-encephalograph—we each play our own little tune. One of us is like the Philharmonic under Toscanini interpreting the "Ride of the Valkyries" on delicate violin strings, while another perhaps is more like "Alexander's Ragtime Band." As Professor Davis puts it, in a more dignified way, "If our hypothesis is correct, it implies that the electrical activity of the brain is an objective index of either the degree or kind of neurological activity which is in

progress. The encephalogram, taken under standard conditions, seems to be quite characteristic for a given person."

The question, of course, which rises at once in the mind of every disciple of the healing art, is whether our jangling orchestras which are murdering the sweet symphonies of life can be brought back to harmony. If the brain is like a radio receiving set, can't we tinker it into tune? Our diathermy machines are working miracles every day with one kind of electrical pulsation, if cantankerous characters are due to twisted patterns of brain-waves, is it ridiculous to look ahead a generation or so and see some discovery that will put the patterns right—"take the sorry scheme entire" and "remold it nearer to the heart's desire?"

Popular misconception imagines that the psychiatrist deals only or chiefly with insanity. On the contrary, most of those who come to the average psychiatrist have no taint of madness, but have become miserable because of some subconscious conflict or other emotional disturbance. They are often, indeed, spoken of as "disturbed," and the electro-encephalograph reveals amazingly the extent and the intensity of the disturbance. It charts an undulating line similar to the one on the seismograph that tells the story of a distant earthquake.

Tommy's Brain Waves

This is shown clearly on the accompanying chart of "Tommy's brain waves," from a paper by Philip Solomon, M.D., of the Emma Pendleton Bradley Home at East Providence, R. I., published in the *Rhode Island Medical Journal*. It was at the Bradley Home, he says, that the electro-encephalograph was built by Dr. Herbert H. Jasper and Dr. Howard L. Andrews, of Brown University. It was tried on Tommy, eleven, "had been destructive, disobedient, hyperactive, impulsive and stubborn all his life. Some days, however, he would be perfectly good, and on other days terrible. There seemed to be no reason

ample, overventilation of the lungs will induce seizures, but only in those patients who are subject to seizures

The Most Important Problem

"The demonstration of this specific chemical abnormality is the most important but most difficult problem before us," Dr Lennox states

"So far, physiological and chemical studies have dealt only with body fluids and with organs distant from the brain. We must now work with brains of patients. Advances in surgery make this more feasible than it once was

"Discovery of the specific something in the nerve cells' physiology which causes

them to discharge an abnormal rhythm may require many years. But we can greatly be heartened by recent enlargements of our knowledge of nerve activity"

Not long ago a best seller was entitled, "Why We Behave like Human Beings." Perhaps we are now making discoveries and finding material for another volume on "Why we Misbehave like Inhuman Beings." Misbehavior is not confined to the untunates in the dock of the police court. The high as well as the low have their brain-storms, their disturbed states, their wild, tossing waves of emotion, and a session with the new detecting instrument might reveal that many a one who thinks himself a Caesar is really instead merely suffering from a seizure

Candidates for county coroner in Ohio must be licensed physicians, or have previously served as coroner, according to House Bill 67, passed by both houses of the Ohio General Assembly and signed by the Governor

Pathogenic bacteria given off by human beings and floating in the air cause the major portion of infected wounds originating in the operating room—*Journal of Thoracic Surgery*

A BIG GAIN IN TREATING BREAST CANCER

The chances of curing primary cancer of the breast, one of the most serious aspects of the disease, have increased from forty-six per cent in 1920 to eighty-seven per cent today, Dr Frank E Adair, secretary of the American Society for the Control of Cancer, reported at the annual meeting of the society's board of directors, in Memorial Hospital, 2 West 106th Street.

Dr Adair, who was re-elected secretary of the society, cited the progress as evidence of the value of the educational campaign which the society has carried on for

twenty-four years. He attributed it to the increased attention paid by women to early symptoms indicative of the disease. His figures were based upon a survey at Memorial Hospital, where he is a staff member.

Other officers elected were Dr Frederick F Russell, of the Harvard School of Public Health, president, Dr John J Morton of the Strong Memorial Hospital, Rochester, vice-president, Calvert Brewer, of New York, treasurer, and Dr E B Wilson, also of the Harvard School of Public Health, chairman of the board of directors

It consists essentially of the reports published in the separate issues of the *Journal of the American Medical Association*

The physician has, therefore, in compact form the report of the activities of the Council on Pharmacy and Chemistry. A perusal of these reports will keep the physician abreast of the latest developments in new remedies

CHARLES SOLOMON

The Management of Obstetric Difficulties
By Paul Titus, M.D. Octavo of 879 pages, illustrated. St. Louis, The C V Mosby Company, 1937. Cloth. \$8.50

At last we have a text-book which is not only entirely different, but extraordinarily good. Not at all conventional, not intended for undergraduate students, normals and fundamentals are omitted entirely or passed over lightly, and obstetrical difficulties and emergencies are thoroughly, yet clearly discussed. Gynecological subjects, which touch obstetrics closely, are very properly included, and the chapter on sterility for instance, is as well done as the chapter on forceps or the introduction

The work of Caldwell and Moloy in their morphologic classification of pelves is given more space and is more clearly explained than in any other text-book.

It is rather brief but sufficient bibliographies are appended to every chapter, so that the less advanced students of obstetrics may follow subjects through if they so desire.

The book is not too long, about 800 pages, well illustrated, good looking, and more valuable for specialists than any other text-book on obstetrics this reviewer has seen. It is nothing if not practical and useful, and Paul Titus should feel very proud of his work. It is highly recommended as well-nigh perfect.

CHARLES A GORDON

Physical Therapeutic Methods in Otolaryngology
By Abraham R. Hollender, M.D. Octavo of 442 pages, illustrated. St. Louis, The C V Mosby Company, 1937. Cloth. \$5.00

Since the earliest writings in medicine, physiotherapy has held a variable position in therapeutics. Today, with a volume of this kind, the otolaryngologist can readily determine and evaluate the various modalities. With the recent employment of short wave apparatus, there has been a good deal of confusion. The perusal of the chapter

on short wave will give the reader last-minute and accurate information. All phases of electrotherapy are covered, the various terms explained, and historical notes given.

This is an unusually fine book and will be of great assistance and highly instructive to the physician who has no doubt as to the value of physiotherapy and the place it should occupy in his armamentarium.

SAMUEL ZWERLING

Starling's Principles of Human Physiology
Seventh edition edited and revised by C. Lovatt Evans, F.R.C.P. & H. Hartridge, M.D. Octavo of 1096 pages, illustrated. Philadelphia, Lea & Febiger, 1936. Cloth, \$8.75

The seventh edition of Starling's Human Physiology, edited by Evans and Hartridge, contains a few important changes from the previous one. Somewhat reduced in size it has been revised so as to include discussions of new methods for recording nerve impulses, for the study of the reproductive cycle, and for the investigation of urine formation. The feature of placing appropriate references in the form of footnotes, first introduced in the previous edition, is continued and enlarged upon in the present one.

DAVID I ABRAMSON

The Diagnosis and Treatment of Diseases of the Stomach and Intestines. By William F. Cheney, M.D. (Reprinted from Oxford Monographs on Diagnosis and Treatment) Octavo of 378 pages. New York, Oxford University Press, 1936. Cloth, \$5.50

This monograph is written by one who has had a large experience in internal medicine, and more especially in diseases of the stomach and intestine.

Without reference to the voluminous literature, and in a simple and direct manner, the author describes advances in the methods of diagnosis, and in the treatment of gastrointestinal diseases. In the differential diagnosis of acute gastritis and in the discussion of chronic gastritis the physician will find much of value.

The book is equally divided into two parts, the first dealing with diseases of the stomach, and the second with diseases of the intestines.

The reading matter is well arranged and includes a discussion of the subject in a most comprehensive manner.

IRVING GRAY

practice, as well as in all types of cosmetics, is complete. If one has a favorite prescription, and wants to know whether any particular ingredient is worthy of inclusion, he can find its physical properties, and physiological action, in this section.

Following are chapters on Acne and Facial Blemishes, Baldness, Poison Ivy, Psoriasis, Ringworm and Scabies which are attacked from a therapeutic angle, rather than a diagnostic one. Then are chapters on such cosmetics as clays, cold cream, brilliantine, depilatories, hand lotions and lip preparations, as well as comments on the method and value of skin peeling in acne, permanent waving, etc. Included with these are formulae of prescriptions (hosts of them) arranged so that one may tell which are most satisfactory from a therapeutic and cosmetic standpoint.

One could wish that comments on the effect of repeated permanent waving were included, as an instance of where this book could increase its already great value.

The author's outline in the introduction, giving a method of using the book to refresh the readers' memory on anatomy of the skin,—of characteristics and uses of drugs, etc. is enlightening, and anyone following this procedure will be benefitted.

E ALMORE GAUVAIN

Physiological Principles in Treatment. By Sir Walter Langdon-Brown, M.A. and Reginald Hilton, M.A. Seventh edition. Octavo of 308 pages. Baltimore, William Wood & Company, 1936. Cloth, \$3.00.

The new edition of this well-known book presents a considerable revision over the previous one. Not only are recent advances in physiology discussed, but their pertinence to treatment ably presented. While of necessity the discussion of each subject is brief, the authors have appended a bibliography of recent outstanding monographs and reviews which should prove valuable to those readers stimulated to seek further information.

The subjects of digestion and the circulation are particularly well discussed. One wishes a little more space might have been given to the physiology of respiration.

G B RAY

Food and the Principles of Dietetics. By Robert Hutchison, M.D. and V. H. Mottram, M.A. Eighth edition. Octavo of 634 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$6.75.

This book is more of a teaching manual to give students the elementary facts about the chemistry and physiology of food, than a reference for the medical man. Although the author does touch on therapeutic diets in the last few chapters, the principles outlined are vague and out-of-date according to more recent experimentation in America. Being an English book, their system of weights, measures, and cost are used in all the charts and cost studies. The book covers too many subjects, ranging from the requirements of the body, the chemistry and physiology of food, some pathology, and lastly to therapeutic dietetics. It would seem to the reviewer that this amount of information could easily be divided into more than one book and that more precise and useable data be given. Although some ideas could be gathered as one peruses the pages of this book, it would, no doubt, be more adaptable as a student reference than a book for either the practitioner or dietitian.

MORRIS ANT

Lectures on Embolism and Other Surgical Subjects. By Gunnar Nystrom, M.D. The Abraham Flexner Lectures Series Number Four. Octavo of 213 pages, illustrated. Baltimore, Williams & Wilkins Co., 1936. Cloth, \$3.00.

This series of five lectures, given at the School of Medicine of Vanderbilt University, has made possible the better appreciation of advances made in surgery at the University of Uppsala, Sweden. In a very small volume, the professor has detailed the surgical treatment of embolism, as found in the various cavities of the human body, as well as the superficial locations. The most interesting lecture is that on the treatment of the fracture of the surgical neck of the femur. This alone is worth more than the price of the book. Other lectures touch upon Swedish experiences in treating appendicitis, also a talk on cytology of joint exudates as an aid to diagnosis. An interesting and instructive book for reading at odd moments.

EUGENE W. SKELTON

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1935 with the Comments That Have Appeared in the Journal. Duodecimo of 139 pages. Chicago, American Medical Association, 1935.

This annual reprint contains the reports of the Council that have been adopted during 1935.

RECENT ADVANCES IN INHALATION THERAPY IN THE TREATMENT OF CARDIAC AND RESPIRATORY DISEASE

Principles and Methods

ALVAN L. BARACH, M.D., *New York City*

*From the Department of Medicine, College of Physicians and Surgeons, Columbia University,
and the Presbyterian Hospital*

The purpose of this communication is to interpret the experience of investigators in oxygen therapy during the past two decades and to present other more recent advances in inhalational therapy.

In 1920 the physiological basis for the therapeutic use of oxygen had already been clearly stated.¹ The dangerous consequences of acute oxygen-want had been demonstrated by careful studies in closed chambers in which the air was artificially deprived of oxygen. Barcroft² lived for six days in an atmosphere in which the partial pressure of oxygen was eighty-four mm and in which the oxygen saturation of his arterial blood was eighty-eight per cent. He lay in the chamber racked with headache, with occasional vomiting, faint on exertion and at times able to see clearly only as an effort of concentration. His pulse was fifty per cent higher than its usual level. More severe oxygen-want was shown to create even more serious consequences in which the pulse became fast and feeble, the respiration rapid and shallow, and consciousness greatly impaired or lost. By means of the arterial puncture³ and accurate methods of blood gas analysis,⁴ it was shown that the arterial blood of patients with pneumonia at times contained a markedly diminished oxygen content, frequently sufficient of itself to produce the symptoms above mentioned. During the years 1921 and 1922, it was shown that the administration of forty to sixty per cent

oxygen to patients suffering from pneumonia⁵ and cardiac insufficiency⁷ was capable of raising the arterial oxygen saturation from an abnormally low level to or near the normal value and that clinical improvement frequently followed this procedure.

From that time on numerous reports were made on the therapeutic use of oxygen in various clinical conditions and descriptions of new methods appeared during the same interval. Our purpose is not to review the entire body of this literature but to consider the evidence which is most pertinent to our discussion of the following disease syndromes.

Lobar Pneumonia and Broncho-pneumonia

The effect of adequate oxygen therapy on the mortality rate of patients suffering from either lobar or broncho-pneumonia has been difficult to obtain because of the absence of a sufficiently large control group with which to make comparison with an oxygen treated group. It has been shown by Binger⁸ at the Hospital of the Rockefeller Institute that a positive correlation existed between anoxemia and mortality, thus, the mortality of eighty-three patients with an arterial oxygen saturation above eighty per cent was twenty-four per cent, whereas the mortality of forty-eight patients with an arterial oxygen saturation below eighty per cent was fifty-six per cent. (This

MEDICAL DIRECTORY OF NEW YORK, NEW JERSEY and CONNECTICUT

Announcement

New Designation for the Medical Directory

In 1936 the Laws of New York were revised, Chapter 459, to provide for qualification of psychiatrists by the new Board of Psychiatric Examiners. It is desired that all those physicians in New York State who have received formal qualification by this Board notify the office of the Medical Society of the State of New York, 2 East 103 Street, New York City, at the earliest possible moment of the fact of their qualification. An appropriate designation will be inserted in the new Directory in all such instances.

While there is no blank space on the cards already mailed to the physicians of the State for this new qualification, the fact may be indicated somewhere on the card. If the card has already been returned it is hoped that each such physician will send the information in by personal letter.

PETER IRVING M D, *Secretary*
Journal Management Committee

able variation, should in general be determined by the estimation of continuing impaired function of the lung or heart. In cases of lobar pneumonia, the return of the temperature to approximately normal levels with a proportionate drop in the pulse rate and respiration indicates that oxygen therapy may be withdrawn. In bronchopneumonia, or where there is an excessive moisture in the lung, the termination of oxygen treatment should be undertaken more carefully, because the function of the lung may show a sharp reversal when oxygen therapy is stopped. Under these circumstances, it is frequently advisable to lower the concentration from fifty to thirty-five per cent during the first twenty-four hours and to take the patient out on the following day. The question of dosage will be discussed separately at the end of this paper.

The addition of carbon dioxide, in excess of one or two per cent, to oxygen mixtures in the routine treatment of pneumonia is not warranted since (1) no convincing clinical evidence has been presented in its favor, (2) labored breathing, nausea, and vomiting may result from concentrations above 3.5 and four per cent, (3) if there is any obstructive condition in the respiratory tract, the increased pulmonary ventilation would tend to promote pulmonary edema by increasing the negative intrathoracic pressure.^{17, 18}

The hydrogen ion concentration of the blood in pneumonia is generally within the range of accepted normal values,¹⁹ although carbon dioxide retention has reported in a few cases with widespread pulmonary involvement.^{20, 21} More commonly, the CO₂ content of the arterial blood is lowered during the febrile course of the disease and is higher in convalescence.^{19, 21} The decrease in blood CO₂ represents a compensated alkalosis associated with hyperpnea, in our opinion. When the increased ventilation is due to anoxemia and reduced by oxygen inhalation, the carbon dioxide content of the blood can be expected to rise, a phenomenon which occurs regularly in the relief of cardiac dyspnea by oxygen inhalation.²² The small amount of CO₂ permitted in most closed circuit oxygen therapy apparatus, under 1.5 or two per cent, appears to do no harm whereas concentra-

tions higher than two per cent measurably increase the volume of air breathed and aggravate the dyspnea. The theoretical advantages Henderson and his associates²³ claimed for its use do not justify employment of excess CO₂ except in rare demonstrated cases of acapnia or as an adjuvant to oxygen therapy in accidental asphyxia, such as CO poisoning. Morphine is of value for the opposite reason that it lowers pulmonary ventilation and promotes sleep and rest, but it should be used in conjunction with oxygen therapy since it has been shown that it sometimes results in serious oxygen-want.²⁴

The use of sodium bicarbonate, recommended in certain cases in which the hydrogen ion concentration appeared shifted to the acid side,²⁰ is not indicated in the routine management of the disease since in subsequent reports a condition of acidosis has not been found. A report of an unusual case²⁵ has been used as argument against the administration of sodium bicarbonate in pneumonia.¹⁹ In this patient, a woman forty-seven years old, generalized edema occurred more than a month after onset of illness and following the administration of five to six grams of sodium bicarbonate for a period of five weeks. The patient gave a history of dyspnea on slight exertion for six years and presumably had had circulatory deficiency. Sodium bicarbonate was stopped and during two exposures of forty per cent oxygen a diuresis occurred coincident with a fall in pulmonary ventilation. The improvement which promptly took place is of considerable interest in connection with the diuresis produced in patients with congestive cardiac edema as a result of oxygen inhalation. We wish to point out that the ingestion of the sodium ion over long periods of time in this case is not considered applicable to the disease lobar or bronchopneumonia. Certainly in the presence of a history suggestive of heart disease, sodium should not be administered either in the form of sodium bicarbonate or sodium chloride. However, in peripheral circulatory failure which at times takes place in pneumonia (due to shock), Atchley has found that the intravenous injection of relatively large amounts of normal sodium chloride solution to have been of definite value.²⁶ Al-

group was also partially treated with oxygen.) In Stadie's series,⁹ the mortality of thirty-two patients was twelve per cent for those who had little or no cyanosis (above 80-85% arterial oxygen saturation) and ninety-three per cent for those who had moderately severe cyanosis (below 80-85% arterial oxygen saturation). Barach¹⁰ has reported two series of severe cyanotic pneumonia patients. The first had a mortality of forty-five per cent in 100 cases and the second group 46.7 per cent in a series of 124 cases. Since these patients belonged to the group in which the patient had generally taken a turn for the worse, including the occurrence of definite cyanosis, this mortality appeared lower than that to be expected in severe cyanotic pneumonia untreated by oxygen. Up to the present time, it has not been possible to use the alternate case method in a statistical evaluation of oxygen therapy. The difficulty of allowing a patient with severe oxygen want as revealed by dyspnea, rapid pulse, and cyanosis to exist as a control untreated case is apparent. This situation was made more complicated by the demonstration, in individual cases, that the withdrawal of oxygen therapy during the course of severe pneumonia was followed by cardio-respiratory failure of such severity that a fatal outcome would have taken place unless oxygen therapy had been reinstituted.^{11, 12} During the past seventeen years, the author has had abundant confirmation of the fact that oxygen therapy in patients with severe anoxemia due to widespread involvement of the lungs or to marked cardiac insufficiency is responsible for the continuance of life, and in a certain number prolongs life sufficiently so that a favorable outcome results. The experience of Boothby and Haines¹³ and Moersch and Boothby¹⁴ indicated even more striking benefit in postoperative pneumonia, not only did marked improvement occur incident to the initiation of oxygen therapy, including a characteristic temperature drop, but the occurrence of postoperative pneumonic complication seemed to be definitely diminished when oxygen treatment was begun immediately after operation. M. W. Binger, Judd, Moore, and Wilder¹⁵ reported a smaller incidence of deaths from pneumonia in

1393 cases in which oxygen tents were used than in 1485 cases in which tents were not used. The figures seemed more significant when related to the time of onset of oxygen therapy. In 158 cases in which oxygen was used one to four days after operation, there were four deaths from pneumonia, in forty-seven cases in which oxygen was given five days or more after operation there were eighteen deaths from pneumonia. In an analysis of 261 oxygen-treated cases on the medical wards of the Presbyterian Hospital, the mortality was classified according to the duration of treatment. In forty-seven cases who were treated with oxygen for one day or a part of a day, the mortality was 87.2 per cent, in sixty-nine cases treated for two to three days, the mortality was 62.3 per cent, in 155 cases treated for four or more days the mortality was 39.3 per cent. In the latter group, there were 101 cases treated by nasal catheter (oxygen concentration at that time thirty-two to thirty-five per cent in the inspired air) with a mortality of 43.5 per cent, and thirty-five cases treated in the oxygen room (oxygen concentration fifty per cent with a mortality of 28.5 per cent.¹⁶ Our own data and that from the Mayo Clinic workers indicate clearly the importance of early and effective oxygen therapy in order to test the value of oxygen treatment.

The indication for oxygen treatment is the first clinical evidence of a diminished oxygen tension in the tissues of the body. We have learned to realize that cyanosis does not begin to show itself until a ten per cent diminution in the oxygen saturation of the arterial blood has already taken place and that in patients with severe anemia cyanosis may not be demonstrable even when the oxygen tension of the arterial blood is lowered thirty or forty per cent. We must have recourse then to other signs of an insufficient oxygen supply to the organism. Emphasis should be chiefly given to a rapid pulse out of proportion to the fever, to the existence of anemia even of slight degree, to the presence of a grayish color, to rapid, shallow respiration and to irrationality, in short, to the symptoms of oxygen-want when they are experimentally produced. The duration of oxygen treatment, although subject to consider-

restored to ambulatory activity This effect of oxygen therapy on congestive heart failure due to arteriosclerotic heart disease has been demonstrated in cases in whom chronic cardiac insufficiency was unrelieved by bed rest and the use of digitalis, diuretics, and other treatment. The omission of adequate oxygen treatment is responsible in some cases for persisting decompensation

Group 3 In acute coronary thrombosis, an abrupt interference with the supply of blood to the coronary artery results in a severe oxygen-want to the heart muscle itself Although there are patients who recover without oxygen treatment and still others in whom the closure is so marked as to result in inevitable fatality, there is a large middle group in whom the continuous inhalation of fifty per cent oxygen prolongs circulatory function until convalescence is established²⁸ In some cases, as well as in cases of acute cardiac or respiratory insufficiency from other causes, it is advantageous to give ninety to one hundred per cent oxygen for the first twelve hours, as will be discussed later Since the cardiac muscle is peculiarly dependent for its adequate functioning on a normal oxygen supply, the increased tension of oxygen in the arterial blood in these cases is of critical importance and to our mind the most valuable therapeutic measure in the treatment of this condition In a case that was very carefully observed, the institution of oxygen treatment was followed within one-half hour by a disappearance of the ashen gray color to the face and a slowing and increased volume of the pulse and a disappearance of dyspnea, oxygen was withdrawn after several hours of treatment in order to determine whether the benefit observed was dependent on the maintenance of the increased oxygen supply, with the result that the patient again became dyspneic, of an ashen gray appearance, and the pulse turned rapid and feeble Resumption of oxygen treatment was followed by a similar improvement to that originally obtained and the patient ultimately recovered The management of acute coronary thrombosis has no physiological indication that is more well-founded than the employment of high concentrations of oxygen It is not within the scope of this presentation to review the physiological data which illustrate that the function of the heart muscle is unusually sensitive to oxygen-want, but it may be mentioned that cardiac glycogen cannot be made to disappear by the most strenuous forms of exercise but is known to decrease swiftly when the oxygen concentration of the inspired air is substantially lowered.²⁹

Chronic Pulmonary Disease

In 1927 Campbell and Poulton³⁰ reported that patients with chronic bronchitis and emphysema were markedly improved as the result of residence in an oxygen chamber with forty per cent oxygen Their dyspnea, cough, and sputum diminished, appetite was increased and patients gained weight Measurement of the pulmonary ventilation showed a definite fall In some cases the improvement was transitory, in others it persisted for months Richards and the author³¹ reported the use of oxygen for long periods of time in patients with pulmonary emphysema, fibrosis, and chronic bronchitis, and our results confirm those of the above authors In addition, it has been shown that patients with pulmonary emphysema and varying degrees of fibrosis experience not only a marked subjective relief but a very real improvement in the measurements of respiratory function, such as vital capacity, pulmonary ventilation, restoration of normal or nearly normal arterial saturations Their behavior may be compared with that of the patient with chronic congestive heart failure, with several differences In the first place, they are more apt to develop a deep sleep or even a comatose state for a temporary period In the second place, the waking cough and abundant expectoration which these patients frequently show may entirely disappear during the period of residence in a high oxygen concentration Finally, there is a marked difference in the reaction of the patient to withdrawal of oxygen

In all of these cases it is of primary importance to lower gradually the oxygen concentration of the air breathed, or the symptoms of oxygen deprivation—such as cough, expectoration, and dyspnea—will recur Furthermore, these patients generally do not develop that type of functional reserve that is characteristic of the patient with congestive heart failure If oxygen treatment is totally withdrawn, a recurrence of the original symptoms takes place gradually, for that reason, it has been our practice to provide patients with chronic pulmonary disease, intermittent oxygen treatment when a period of continuous oxygen therapy has terminated This applies to pulmonary fibro-

though no general indication exists for the employment of either sodium bicarbonate or sodium chloride, there appears to be no contraindication for the use of either if special circumstances arise which provide adequate indication

Cardiac Insufficiency

Although it had been shown in 1921 that the oxygen concentration of both arterial and venous bloods could be substantially elevated by the inhalation of fifty per cent oxygen,⁷ the special therapeutic effectiveness of the continuous inhalation of oxygen in various types of congestive and coronary heart failure were not made clear until studies started at the Presbyterian Hospital in 1930.²⁷ Since that time, 120 patients have been reported in various communications in which oxygen therapy was carried out. We may divide these cases into three groups (1) congestive heart failure associated with rheumatic disease of the heart, (2) congestive heart failure with nonrheumatic disease, including either arteriosclerotic or coronary heart disease, (3) acute coronary thrombosis

In the first group, the special value of oxygen inhalation is in the treatment of acute decompensation, in which the inhalation of fifty per cent oxygen is often of critical help in relieving the dyspnea and in removing the effects of arterial anoxemia on an overburdened heart muscle. When the acute symptoms of cardiac insufficiency are relieved, the patients with chronic rheumatic heart disease generally show little permanent benefit from a continuance of oxygen treatment. Frequently a state of compensation is maintained with the help of continuous oxygen, but the patient influenced by the rheumatic virus is less apt to show a more lasting improvement from oxygen therapy than the patient with congestive heart failure due to arterial sclerotic disease

Group 2 When congestive heart failure takes place in a patient suffering from arterio-sclerotic heart disease, the effects of continuous oxygen therapy are more striking. Dyspnea and restlessness begin to be relieved within a period of three or four hours and after two or three days are often completely relieved. The arterial oxygen saturation is restored to normal or raised slightly above normal within the first hour,

between the third and the sixth day after the initiation of treatment in favorable cases, a diuresis takes place which in many instances has been shown to be specifically dependent on the increased concentration of oxygen in the inhaled air and not due to further rest in bed. It has been shown in carefully studied cases that the diuresis may abruptly cease when the oxygen concentration is lowered to that of the atmosphere. There is a marked improvement in cough, orthopnea, and insomnia in cases in which dyspnea and insomnia have been previously severe. Oxygen treated patients may develop a state of stupor, with irrationality when aroused, lasting from one to five days. In our experience this is a sign of previously existing oxygen-want affecting the cerebral tissues and is a reaction, a sudden change in oxygen tissue tension. It is uniformly followed by a lucid and cheerful mental state, and is an indication for continuation rather than interruption of treatment.

Of the changes in respiratory metabolism, the most striking is the rise in the carbon dioxide content of the arterial blood. This may increase from ten to twenty volumes per cent, beginning on the first day and continuing for a week to ten days. As the patient regains compensation, the blood CO_2 progressively falls. This phenomenon has been interpreted as a mechanism developed by the patient in order to permit an adequate exit of carbon dioxide under conditions of a lowered pulmonary ventilation which oxygen treatment makes possible. In these patients the pulmonary ventilation may be reduced in a week from twelve liters per minute to six liters per minute because of the higher tension of oxygen in the inspired air. The increase in the concentration of carbon dioxide in the arterial blood makes possible a larger output of CO_2 per unit of breathing, in that way preventing an undue retention of CO_2 in the body tissues.

In these patients, after two or three weeks of fifty per cent oxygen, it is advisable to lower the oxygen concentration gradually. If the chamber or tent has been previously used, the double nasal catheter (or the catheter in the oral pharynx) may be employed at five liters per minute, yielding an oxygen concentration of approximately thirty-eight to forty per cent, during the succeeding two weeks. A gradual lowering of oxygen concentration should be achieved by reducing the flow of oxygen one liter per minute each two or three days. When this technique is carried out, no sharp reversal of circulatory function is apt to take place, and the patient may be

during the inspiration of the gas and decreasing the effort required. During expiration there is a more uniform and complete emptying of the alveoli due to the distending effect on the smaller tubular structures which otherwise tend to collapse during expiration.

We have also employed a hood which fits with a rubber collar around the neck, enclosing only the head, for treatment of these patients, particularly those in status asthmaticus and for those in whom more continuous treatment is desirable. This method is more comfortable to patient.

In the treatment of status asthmaticus, hypertonic solutions are of help in reducing bronchiolar edema. Intravenous injections of one hundred c.c. of fifty per cent sucrose is especially recommended. Mild sedative is desired, as may be obtained with codeine and luminol, but morphine except in small doses is dangerous since it may result in respiratory failure. The relief of status asthmaticus in apparently moribund patients by inhalation of helium-oxygen mixtures has been confirmed by Maytum, Prickman, and Boothby.²³

The relief which helium-oxygen mixtures under slightly positive pressure induces creates in the patient an artificially imposed betterment in pulmonary ventilation which is followed by an actual improvement in bronchial spasm and total respiratory function.

Obstructive Dyspnea in the Upper Air Passages

In obstructive conditions of the trachea, larynx, and larger bronchi, helium-oxygen mixtures with and without slightly increased positive pressure have been used, the physiological principle being comparable to that of its use in asthma. There is one difference, namely, that constriction of the smaller bronchial tubes takes place in the asthmatic patient during expiration owing to the termination of the inflating effect of the negative pressure within the chest and in some cases to a positive pressure expiratory force which locks air in the alveoli by further compressing the bronchioles. In the respiratory tubes outside the chest this effect is absent and the cartilaginous rings of themselves tend to maintain the

integrity of the lumen. Since Moore and Binger²⁴ have shown that expiratory obstruction has few if any pathological consequences in the lungs, whereas obstruction of the inspiratory cycle has the dangerous results of producing pulmonary congestion and edema, and in some instances emphysema,^{25, 26, 27} the effect of positive pressure is itself of considerable value in obstructive dyspnea.

Patients with obstructive lesions in the larynx have been sufficiently relieved of their dyspnea by continuous inhalation of helium-oxygen mixtures as to avert tracheotomy in some instances.^{28, 29} In one recent case, a threatened asphyxial death due to a tumor pressing on the trachea and larger bronchi was averted by helium-oxygen inhalation. The tumor proved to be radium sensitive and in two weeks the patient was entirely free from dyspnea even in the absence of helium treatment. The function of helium in this group is to provide relief to obstructive dyspnea until such time as the cause of the pathology is removed and the disease process clears up. A detailed study of a series of twenty cases is shortly to be presented by Kernan and the author in some of which tracheotomy was averted by helium-oxygen treatment.

Edema of the Lungs

The use of positive pressure in the treatment of obstructive dyspnea has been extended to the treatment of acute pulmonary edema occurring as a complication of pneumonia or as a direct manifestation of cardiac insufficiency. We are unable at this time to review in detail the pathological physiology of this disease entity. However, it is plain that there is an increased exudation of serum from the capillary blood vessels within the lung. There is generally an increased accumulation of blood in the capillaries so that, in many instances, it is possible to assume an increased pressure is present in these vessels, with a consequent tendency for them to leak serum into the alveolar spaces. There is an additional hypothesis that the right heart expels a greater amount of blood than the left ventricle can handle,³⁰ but this theory merits separate discussion.

It has been found clinically, however,

sis whether caused by old tuberculosis or nonspecific infection or irritation, or whether associated with bronchiectasis or emphysema. Inhalations of one hundred per cent oxygen through a portable face tent or mouthpiece apparatus may be given for one-half hour two or three times a day. In some cases nasal oxygen, two to four liters per minute, is given at night. The value of maintaining oxygen treatment consists in the periodic alleviation of a continuous oxygen deficit and in intermittent relief of an over-distended condition of the lung.

Asthma

Oxygen treatment has been used in severe asthma in the attempt to supply an adequate oxygen tension in the alveolar air and thus overcome the threat of asphyxiation induced by the narrowed bronchi and bronchioles. Although some benefit has been achieved in this way, the significant disturbance in severe asthma appears to be due to an inability on the part of the patient to provide himself with adequate pulmonary ventilation except at a cost of a dangerous interference with the physiological mechanics of breathing. In order to deliver to the alveolar spaces a velocity of air flow that provides comfort, the patient develops a pathologically elevated intrapleural and intrathoracic negative pressure of such degree as to initiate respiratory fatigue, which may progress to cessation of respiratory activity, congestion, and edema in the lung and circulatory failure. The increased negative pressure within the chest aids the inlet of blood into the right heart and into the lungs but handicaps the outlet of blood from the left ventricle into the extrathoracic aorta, with the result that the pulse becomes rapid and small in volume and the lungs accumulate blood. In addition there is a suction action on the capillaries in the alveolar wall tending to produce an exudation of serum into the alveolar spaces. Furthermore, there takes place an exudation of seromucous nature into the bronchiolar passages themselves which additionally increases the obstruction.

To counteract this pathological physiology, helium was proposed as a therapeutic gas to be used with oxygen in con-

centrations comparable to that present in air.³² The decreased specific gravity of helium in relation to nitrogen makes possible a mixture of twenty-one per cent oxygen and seventy-nine per cent helium which has almost one-third the density of air and requires almost one-half the physical effort to deliver such a gas through a constricted orifice.

Over forty cases of severe continuous asthma, including ten instances of status asthmaticus, have been treated by intermittent or continuous inhalation of helium-oxygen mixtures, generally with positive pressure in addition. These cases had all been refractory to adrenalin and had failed to respond to other measures. In the grave cases of status asthmaticus, the method proved to be a life-saving measure. In more chronic cases in a period from one to five days of intermittent treatment, patients have been restored to a state of adrenalin sensitivity and have become free from continuous asthma, although a permanent cure of the state of asthma has not been thereby achieved. However, these patients have been able to return to their homes or occupations in the majority of instances. In other cases, return of severe asthma has occurred after a short interval and became an indication for repetition of the treatment.

In the patient with chronic, more or less continuous asthma, the mixture may be breathed for periods of from one-half to three hours through a mouthpiece or mask closed circuit rebreathing apparatus. The dyspnea is relieved, varying with the extent and character of the bronchial narrowing, between fifty and one hundred per cent. The rales are either greatly diminished or disappear. This applies particularly to the rales present during inspiration. The pathologically elevated negative intrapleural pressure is reduced, the pulmonary ventilation is lowered, and the circulation is improved. As the treatments are repeated, the patient becomes more rested, sleep takes place, and adrenalin sensitivity is gradually restored. A slight increase in positive pressure during the inhalation of the helium-oxygen mixture, such as from one to five cm of water, is of decided value in increasing the velocity of entrance of the mixture into the lung.

oxygen in physical solution in the blood provided by the inhalation of one hundred per cent oxygen is of critical value. High concentrations are of special importance in the author's opinion, in acute coronary thrombosis. Sayers⁴⁸ found that animals may survive concentrations of one hundred per cent oxygen for as long as sixteen hours a day, and human beings have been exposed without apparent harm to one hundred per cent oxygen for as long as ten hours a day⁴⁸. The author found that when rabbits were exposed to one hundred per cent oxygen for sixteen hours a day and fifty per cent oxygen the remainder of the period, pathological section of their lungs revealed scattered areas of edema in the alveolar cells within three to five days, and after exposure for periods as long as two weeks evidence of interstitial pneumonia. When the period of inhalation of one hundred per cent oxygen was lowered to twelve hours a day, these pathological changes did not take place. It appears, therefore, that patients with evidence of severe anoxemia may tolerate the inhalation of 100% oxygen for approximately 12 of the 24 hours.

The inhalation of one hundred per cent oxygen for six to ten hours a day has been used by Fine⁴⁹ and his collaborators in the treatment of abdominal distension, the principle being that the nitrogen and other gases in the intestine will diffuse through the pulmonary capillaries more quickly when there is not an opposing pressure of oxygen in the alveolar air. In certain cases of acute cardiac insufficiency that follow operations, the inhalation of one hundred per cent oxygen for a limited period may be of special value. The usefulness of pre- and postoperative oxygen treatment in patients with advanced heart disease, as reported by Barach, Richards, and Parsons,⁵⁰ indicated that severe postoperative reactions could be avoided to a large extent in this way.

Among the technical methods for the administration of oxygen, the oxygen chamber appears to be the most comfortable to the patient. Instead of using a motor blower unit for ventilating the chamber, as employed by Stadie,⁵¹ Barcroft,⁵² Campbell and Poulton,⁵³ and Binger,⁵⁴ the author⁵⁵ accomplished a

similar purpose by thermal circulation within the chamber. During the past year, a hospital room in the private pavilion of the Presbyterian Hospital has been converted into an oxygen room, using the same principle of air circulation. Along one wall three horizontal banks of brass pipe were erected through which the hospital brine circulated. Each bank of coils was equipped with a thermostatic control valve which turned off the brine when the temperature fell below 35°F. Under the coils a metal trough caught the condensed water. At the opposite side of the chamber the steam radiator was placed and to it was attached a thermostatic control. The window of the room was made leaktight by covering it with a rubber-gasketed window frame. The various fixtures in the bathroom were made leaktight and the wall covered with several coats of leaktight paint or enamel. The door entering the room was lined with a rubber gasket so as to be made leaktight when closed. A long handle was employed in order to exert greater pressure on the rubber gasket and to facilitate opening and closing the door. A rubberized curtain was suspended inside the door in order to prevent a rapid loss of oxygen when the room was entered. If the curtain is not pushed to one side when the door is opened, but allowed to remain in place until the door is closed, frequent entrances or exits from the room may be made with small loss of oxygen. The curtain is superior to a lock cabinet in saving of oxygen. A panel is placed in front of the brine coils which is perforated by holes one-half inch in diameter along the upper three feet of the panel and the lower three feet as well. This allows the cold air to pass downward behind the panel and through the perforations into the room and the warm air to rise and enter the top of the panel. The perforations along the lower margin of the panel may be closed by an overriding screen so that the volume of cold air can be controlled. In this chamber, temperatures between 50 and 80° F may be obtained as well as a wide range of relative humidity, as low as fifteen per cent. The chamber is generally maintained at a temperature between 60 and 70° F with a relative humidity of thirty

that positive pressure inhalation of helium-oxygen mixtures or of oxygen or of air will result in a swift clearance of the symptoms of pulmonary edema. This effect was first described in animals by Haven Emerson,³⁹ when he observed that edema of the lungs produced by adrenalin cleared up when artificial respiration was employed. The first clinical example of the successful treatment of pulmonary edema by positive pressure respiration was reported by Norton⁴⁰ in 1897, using the Fell-O'Dwyer forced respiration apparatus.⁴¹ Poulton⁴² has reported beneficial results from its use in cases of paroxysmal dyspnea (cardiac asthma) and has used the suggestion of Plesch⁴³ that it be used in edema of the lungs with "rattling" respiration. We have made a preliminary report on the treatment of acute pulmonary edema by positive pressure respiration,⁴⁴ and will report (separate publication) the physiologic effects on the circulation of breathing under slightly increased positive pressure.

In this general review we will confine ourselves to a report of the method of application and the clinical results. Patients with acute edema of the lungs occurring as a sequence of cardiac insufficiency in pneumonia, cardiac disease or prolonged asthma have shown a definite clearance of edema as a result of breathing under a positive pressure of approximately five cm of water. The signs of edema disappear within five to twenty minutes and continue to be absent as long as the pressure is applied or until the original cause of the edema has been removed. From the report of Norton, it may be expected that edema of the lungs produced by chemical irritants may also be controlled by the application of positive pressure to the inspired air.

When tracheotomy is performed on patients in whom obstruction in the larynx has existed for a considerable period, a profuse production of edema fluid takes place which requires aspiration and suction at frequent intervals for many days and sometimes weeks. Woodman⁴⁵ showed that breathing against positive pressure during expiration resulted in an abrupt checking and disappearance of the previously formed edema. Kernan and the author (to be published)

have confirmed this finding and shown that the application of five cm of water during the expiratory cycle was followed by the clearance of serous and mucous fluid in the tracheobronchial tree. With a gradual lowering of the positive pressure the patients became free from the tendency to form edema within two or three days. In this type of case, the sudden removal of a previously existing backward pressure on the alveolar capillaries is apparently followed by an increased permeability. When the backward pressure is again applied and then gradually lowered, the leakage of serum is stopped.

Methods of Administration

The question of dosage in oxygen therapy has received less consideration than it deserves. Physiologically it may be argued that a concentration of oxygen in the inspired air which is capable of relieving the anoxemia is indicated. Because of the technical difficulties of determining the oxygen saturation of the arterial blood and because clinical indications are not sufficiently accurate, the custom of giving between forty and sixty per cent oxygen has developed. Evans⁴⁶ has called attention to the fact that the administration of forty per cent oxygen did not raise the arterial oxygen saturation to the normal level in a large number of cases in earlier reports of the author and suggested the inhalation of one hundred per cent oxygen to patients with pneumonia. Extensive experimental investigation in animals has shown that very rich oxygen mixtures, between eighty and one hundred per cent, produce irritant inflammatory lesions in the lung when used continuously for two to five days.⁴⁷ However, oxygen concentrations under seventy per cent have no such influence. The author has kept adult and infant rabbits continuously in a concentration of sixty per cent oxygen for three months without apparent harm.

In most instances, the employment of fifty per cent oxygen in a tent, chamber or with the use of the double nasal catheter or oropharyngeal catheter is sufficient to overcome the anoxemia present. However, there are patients with acute cardiac insufficiency in whom the increased

June 15, 1937]

thor described a large and small oxygen face tent made of transparent plastocoele which fit over the bridge of the nose and may easily be molded to the conformation of the patient's face.⁶⁸ Oxygen concentrations in the inspired air between forty and sixty per cent may be obtained at a flow between five and ten liters per minute. The simplicity, effectiveness, and inexpensiveness of this oxygen face tent are its chief advantages. In clinical practice, many patients have found it more comfortable than the nasal catheter. Although it does not provide the cool, dry atmosphere of a well-ventilated oxygen tent, the oxygen concentration secured is as great and often higher than that obtained in the oxygen tent at comparable rates of oxygen administration.

The administration of helium with oxygen instituted the development of apparatus in which all inward leaks had to be rigidly excluded. This required a closed circuit apparatus with the use of soda lime and also provision for administering the mixture under slightly increased positive pressure. A mouthpiece or mask rebreathing apparatus has been employed for short periods of administration. Two types will be presently described in detail. They may be used for the administration of oxygen under positive pressure. For more continuous use, a hood has been devised which marks closure at the neck. This type of neck closure was suggested by Benedict's helmet apparatus for measuring gaseous metabolism.⁶⁹

In all these methods it is of importance that inward leaks be prevented or rapidly repaired when found. Pressure of one to five cm of water is frequently advantageous, although two or three cm pressure is ordinarily used. A detailed description follows.*

Helium-Oxygen Rebreathing Apparatus With Positive Pressure

The apparatus is suggested for its small requirement of gas. A flow of two liters per minute of the helium-oxygen mixture

is sufficient to maintain a constant percentage of the respective gases in the circuit. The carbon dioxide eliminated by the patient is absorbed by the soda lime in circuit.

The 6,000 r.p.m. motor permits adequate circulation with no resistance, and in addition is capable of delivering the gases in circuit at any pressure desired. A pressure control valve and rheostat give accurate control of pressure in expiration and inspiration.

With the by-pass valve, nitrogen in the patient's lungs can be eliminated in the open air and not into the gas circuit where it would dilute the helium mixture. The mouthpiece valve traps the gases in machine when the latter is not in use and in this way large quantities of the gas are not wasted.

The entire mechanism is enclosed in an acoustical lined box to protect the various parts and deaden the noise of the high speed motor.

The mask attachment is used when the mouthpiece is found trying to the patient. For longer periods, the hood tent can be used, the atmosphere passing through an ice can before entering the hood. (Fig 1-2)

TO PREPARE APPARATUS FOR USE

- 1 Open pressure valve D full (counterclockwise), turn by-pass valve E into circuit (handle horizontal), open mouth piece valve G to air (handle horizontal)
- 2 Fill bag with gas mixture through inlet A, turn on motor (rheostat to highest speed), cap hand over outlet on mouthpiece valve G, and turn handle to vertical position. Allow to run this way for one-half minute and then turn handle on by-pass valve E to vertical position till bag empties. After bag is empty, turn valve handles of E and G horizontal, and stop motor
- 3 Repeat No 2 above, two times

TO ADMINISTER GAS

- 1 After filling bag for third time, regulate flow of gas (see below)
- 2 By-pass valve E (handle vertical), clamp patient's nose, and put mouthpiece in his mouth. Turn handle of mouthpiece valve (G) to vertical position
- 3 Allow patient to take eight to ten breaths, then turn by-pass valve (E) handle to horizontal position, and turn motor on to full speed
- 4 Regulate pressure as follows for pressures higher than two cm turn motor on full and regulate pressure with pressure valve (D), for pressures less than two

* The apparatus outlined in this article may all be made by following the descriptions in the text. Manufacturing concerns interested in the equipment are The Oxygen Therapy Service, 247 East 86th St., N. Y. C., the J. H. Emerson Co., 22 Cottage Park Ave., Cambridge Mass., and W. E. Collins, 555 Huntington Ave., Boston, Mass.

to forty per cent. This type of chamber appears as an ordinary hospital room and is therefore less apt to create apprehension in a nervous patient.

The oxygen is admitted from an adjoining room through a silencer, so that during operation there is no noise whatsoever. A concentration of fifty per cent oxygen is maintained by admitting 800 to 1000 cubic feet of oxygen a day, four to five 220 cubic foot tanks. Soda lime is not employed, since this intake of oxygen is sufficient to wash out the carbon dioxide given off by patient and nurse.

The principle of thermal circulation has also been applied to the oxygen tent.⁶⁶ Provided a ten degree drop in temperature below that of the outside air can be obtained, this type of tent may be employed. Our own preference is for a motor-driven oxygen tent, since a wide range of ventilation may be obtained with greater swiftness and accuracy.⁶⁷ Since several fires have been reported in oxygen tents, it is important to maintain the precaution of not admitting any inflammable object within the tent. The occurrence of fire cannot result from the motor blower unit, since the motor is in air and not within the oxygen atmosphere. An oxygen testing board should be part of the equipment of the tent, for it is important to test the oxygen concentration two or three times daily in order to be certain that the patient is receiving the oxygen concentration prescribed.

The open box method of administering oxygen was developed by Burgess.⁶⁸ The oxygen concentration is maintained at a satisfactory level at the lower part of the tent, where it is closed off, at the upper part of the hood the concentration diminishes as it is exposed to the outside air. This method appears to have special advantages for infants and children, although it has also been used for adults. Caution must be exercised not to place it near an open window or a strong draft, as the oxygen would thereby be quickly washed out. It has the advantage of simplicity and inexpensiveness, although the control of temperature and humidity is not as effective as it is in a motor-driven tent. A modification of the box method has been recently devised for giving ninety-five per cent oxygen.⁶⁸

A nasal catheter may be employed in

the nasopharynx either as a single or a double tube. According to this technique,⁶⁹ the catheter is passed into the nostril until the tube just touches the posterior pharyngeal wall, it is then withdrawn slightly so that the irritating effect of this contact is removed. The terminal one inch of the catheter, generally #10 or #12 French, should be perforated with small holes so that a single stream of oxygen does not impinge on the mucous membrane. With the double nasal catheter a flow of five liters per minute will result in an oxygen concentration in the inspired air between thirty-seven and forty per cent, with the use of eight liters per minute oxygen concentrations between forty-two and forty-four per cent may result. Waters and Wineland⁶⁰ report still higher oxygen concentrations when the catheter is placed in the oral pharynx opposite the uvula. These results vary somewhat with the rate of respiration, being lower at slower respiratory rates.⁶¹ A catheter carrier is described by Marriott and Robson.⁶² This consists of an adaptation of a laryngologist's head mirror strap which hold a metal cannula in place to which is attached soft rubber catheters. Bullowa prefers a metal nasal inhaler which fits just inside the nostrils, although in our experience concentrations of oxygen lower than those obtained by a double nasal catheter, result at similar rates of flow.⁶³ Poulton and Adams describe higher concentrations in the oxygen tent than those obtained by nasal catheters at similar rates of flow.⁶⁴ Our preference is also for the oxygen tent provided that it is skillfully administered and the oxygen concentration of the atmospheric air frequently tested. But it must not be lost sight of that the nasal catheter is itself an effective method which is capable of widespread usefulness.

Campbell⁶⁵ has described a box mask enclosing the face and neck which consists of an aluminum cardboard frame to which linen is attached. The latter moistened with water tends to cool the apparatus. In a similar device developed by Taylor,⁶⁶ oxygen and air are first passed through a refrigerating cabinet. A manufacturer, Lombard,⁶⁷ has advertised an inhaler which covers the nose and mouth. In a recent communication the au-

thor described a large and small oxygen face tent made of transparent plastocoele which fit over the bridge of the nose and may easily be molded to the conformation of the patient's face⁶⁸. Oxygen concentrations in the inspired air between forty and sixty per cent may be obtained at a flow between five and ten liters per minute. The simplicity, effectiveness, and inexpensiveness of this oxygen face tent are its chief advantages. In clinical practice, many patients have found it more comfortable than the nasal catheter. Although it does not provide the cool, dry atmosphere of a well-ventilated oxygen tent, the oxygen concentration secured is as great and often higher than that obtained in the oxygen tent at comparable rates of oxygen administration.

The administration of helium with oxygen instituted the development of apparatus in which all inward leaks had to be rigidly excluded. This required a closed circuit apparatus with the use of soda lime and also provision for administering the mixture under slightly increased positive pressure. A mouthpiece or mask rebreathing apparatus has been employed for short periods of administration. Two types will be presently described in detail. They may be used for the administration of oxygen under positive pressure. For more continuous use, a hood has been devised which marks closure at the neck. This type of neck closure was suggested by Benedict's helmet apparatus for measuring gaseous metabolism.⁶⁹

In all these methods it is of importance that inward leaks be prevented or rapidly repaired when found. Pressure of one to five cm. of water is frequently advantageous, although two or three cm. pressure is ordinarily used. A detailed description follows.*

Helium-Oxygen Rebreathing Apparatus With Positive Pressure

The apparatus is suggested for its small requirement of gas. A flow of two liters per minute of the helium-oxygen mixture

is sufficient to maintain a constant percentage of the respective gases in the circuit. The carbon dioxide eliminated by the patient is absorbed by the soda lime in circuit.

The 6,000 r.p.m. motor permits adequate circulation with no resistance, and in addition is capable of delivering the gases in circuit at any pressure desired. A pressure control valve and rheostat give accurate control of pressure in expiration and inspiration.

With the by-pass valve, nitrogen in the patient's lungs can be eliminated in the open air and not into the gas circuit where it would dilute the helium mixture. The mouthpiece valve traps the gases in machine when the latter is not in use and in this way large quantities of the gas are not wasted.

The entire mechanism is enclosed in an acoustical lined box to protect the various parts and deaden the noise of the high speed motor.

The mask attachment is used when the mouthpiece is found trying to the patient. For longer periods, the hood tent can be used, the atmosphere passing through an ice can before entering the hood (Fig 1-2).

TO PREPARE APPARATUS FOR USE

- 1 Open pressure valve D full (counter-clockwise), turn by-pass valve E into circuit (handle horizontal), open mouth piece valve G to air (handle horizontal).

- 2 Fill bag with gas mixture through inlet A, turn on motor (rheostat to highest speed), cap hand over outlet on mouthpiece valve G, and turn handle to vertical position. Allow to run this way for one-half minute and then turn handle on by-pass valve E to vertical position till bag empties. After bag is empty, turn valve handles of E and G horizontal, and stop motor.

- 3 Repeat No 2 above, two times

TO ADMINISTER GAS

- 1 After filling bag for third time, regulate flow of gas (see below).

- 2 By-pass valve E (handle vertical), clamp patient's nose, and put mouthpiece in his mouth. Turn handle of mouthpiece valve (G) to vertical position.

- 3 Allow patient to take eight to ten breaths, then turn by-pass valve (E) handle to horizontal position, and turn motor on to full speed.

- 4 Regulate pressure as follows for pressures higher than two cm. turn motor on full and regulate pressure with pressure valve (D), for pressures less than two

* The apparatus outlined in this article may all be made by following the descriptions in the text. Manufacturing concerns interested in the equipment are The Oxygen Therapy Service, 247 East 56th St., N. Y. C.; the J. H. Emerson Co., 22 Cottage Park Ave., Cambridge Mass.; and W. E. Collins, 555 Huntington Ave., Boston, Mass.

Fig 1 and 2

cm open pressure valve D as wide as possible, and slow motor with rheostat till desired pressure is obtained. Pressure is read on manometer F.

TO REGULATE GAS FLOW

1 In filling bag run gas mixture as rapidly as gauge will allow.

2 The gas mixture should be run at two liters per minute constantly while the patient is using the machine. In addition a flow of oxygen equal to the oxygen consumption of the patient is added.

3 If the patient is not holding the mouthpiece tightly, leakage will occur with the

consequent emptying of the bag. An increased flow will be found necessary.

TO USE MASK

1 Disconnect mouthpiece valve and connect in its place the two lengths of non-kinkable tubing attached to the outlets of the mask.

2 Use clamp on inlet tube of mask in place of mouthpiece valve.

3 Proceed as above.

PRECAUTIONS

1 It is imperative that no nitrogen be allowed to get into the circuit at any time. Small quantities of nitrogen tend to vitiate results.

2. If patient wishes to get off the apparatus for any reason, turn handle of mouthpiece valve G to horizontal position, and stop motor. Remove patient. Do not stop flow of gas into the inlet A unless patient will stay off machine for more than two or three minutes. To replace patient on machine, proceed as above.

3. At end of treatment, shut off gas supply from tank, and be certain that handle of mouthpiece valve G is in horizontal position, so that gases in apparatus will not escape.

4. If the apparatus stands idle for an interval of two to three hours after a treatment, it is not necessary to again purge the circuit. If the apparatus stands idle overnight, it is wise procedure to purge it before use.

5. From time to time while apparatus is in use, the bag will fill to capacity. It should be emptied half way by turning by-pass valve E to vertical position for a few seconds. The gas flow, motor, etc., need not be touched during this operation.

6. The soda lime should be changed after ten hours of use.

Pressure Head Tent

DIRECTIONS FOR ASSEMBLY OF APPARATUS

1. Disconnect bag B from helium rebreather and connect the inlet and outlet tubes of the apparatus which were formerly connected with the bag with a length of rubber tubing.

2. Disconnect mouthpiece valve G. The two tubes (suction and pressure) leading from the rebreather are connected to the cooler and hood as follows:

a. The suction tube is connected directly to the hood.

b. The pressure tube is connected to one arm of the cooling system. The other arm of the cooling system is then connected to the hood.

DIRECTIONS FOR OPERATION

1. Turn on the motor of the unit, open one sleeve of the hood, and place hood over patient's head. See that the rubber collar fits tightly around the neck.

2. Rapidly purge oxygen with a needle valve into the apparatus through petcock A until all the air is washed out (300 liters usually suffice).

3. Add the helium-oxygen mixture at fifteen liters per minute until the gas mixture desired is obtained. Shut the open sleeve of the hood and regulate flow of the helium-oxygen mixture to two liters per minute. Add 200 to 400 c.c. of oxygen per minute to provide for the oxygen consumption of the patient.

4. Immerse pressure control tube into the water bottle to a depth equal to the pressure desired for the patient.

Small Apparatus for Administration of Helium and Oxygen in Treatment of Asthma

A small flow of gas is necessary to run this apparatus, two liters per minute of the helium-oxygen mixture being sufficient.

The expiratory pressure is easily controlled by addition or removal of water from the water bottle. Although the simplicity and inexpensiveness of this small apparatus are valuable, the helium-oxygen rebreather is to be preferred because it is more effective (Fig 3-4).

For Administration of Helium-Oxygen Mixtures with Small Apparatus

1. Immerse pressure tube B to a depth equal to the desired expiratory pressure (Fig 3).

2. Close off inlet G and run gas mixture in through inlet K.

3. Pinch neck of bag J and fill with gas mixture. Start patient breathing from mouthpiece E and release neck of bag. Clip patient's nose. Run gas into K at rate of ten to fifteen liters per minute for three minutes.

4. Reduce flow of helium-oxygen mixture to two liters per minute and add a flow of oxygen equal to the oxygen consumption of the patient.

5. Change soda lime in CO₂ filter after four hours of use.

Directions for Use of Helium Water Bottle

Fill bottle with water to mark W on scale (Fig 4).

Hook up gauge, needle valve and water bottle to tank as shown.

Turn handle D on gauge counterclockwise till it comes out of gauge. Close needle valve E (handle turned clockwise).

Open tank valve A—contents of tank will be recorded on gauge B.

Replace handle D of valve and turn clockwise till pressure of five lbs registers on gauge C.

Turn handle of needle valve E counterclockwise till float in water bottle registers desired flow.

This apparatus is calibrated for a twenty-one per cent oxygen-seventy-nine per cent helium mixture, and corrected to 0° C, and 760 mm mercury pressure. It will not record accurately for any other gas mixture.

The water level in gauge must be kept at mark W at all times

General Considerations

The purpose of inhalational therapy may be stated in general as the relief of dyspnea, viewing dyspnea both as a subjective sensation and an objective pathological process. The bearing of the results of inhalational therapy in the various conditions reviewed above may be briefly discussed. The primary objective of this type of treatment must be mainly thought of as an attempt to provide an adequate tension of oxygen in the tissues and to remove the carbon dioxide formed in them as the result of oxidation. Emphasis has recently been put on the proprioceptive reflexes emanating from the lungs and the chest wall as the cause of cardiac dyspnea.⁷⁰ Although it can be readily admitted that the sensation of air hunger is aroused intracerebrally from nerve impulses traversing the Hering-Breuer arcs and related nerve pathways, the objective pathological process of labored breathing is closely dependent on chemical factors involved in gas exchange. In studies of Richards and the author, a prompt diminution of both the volume of the pulmonary ventilation and the effort employed in breathing take place in patients with congestive heart failure after inhalation of high oxygen atmospheres. In our opinion, there is, therefore, a

very significant relation between the chemical factors which are operating and the cause of dyspnea. The interpretation of cardiac dyspnea on the basis of disturbed proprioceptive pulmonary reflexes limits itself simply to an explanation of the sensation and does not aid a therapeutic or physiological recognition of cardiac dyspnea.

The absence of alkalosis in congestive heart failure is indicative of a volume of pulmonary ventilation designed to accomplish as nearly normal a gas exchange as possible and evidence against a reflex stimulation of respiration as the predominating cause of cardiac dyspnea. In pneumonia a compensated alkalosis is sometimes found, in which case local reflex stimulation may play a part in addition to oxygen-want. It is, however, in obstructive dyspnea that proprioceptive reflexes have a more profound physiological significance. When there is constriction of any part of the passageway between the pharynx and the lungs, an increased effort is required to provide the accustomed pulmonary ventilation. In this type of dyspnea the inhalation of one hundred per cent oxygen modifies the dyspnea only to a slight extent unless pathological changes have taken place in the lungs. As the result of the use of helium, at times with oxygen concentrations which are less than those in the atmosphere, the relief of dyspnea has been shown to be

Fig 3 Small apparatus for administration of helium and oxygen. (B) Pressure tube, (C) Water bottle, (D) Non-kinkable tubing, (E) Mouthpiece, (F) Mouthpiece holder, (G) Gas inlet, (H) CO₂ filter, (J) Gas bag, (K) Gas inlet, (L) Clamp support.

due to a decreased effort in providing an accustomed velocity of gas flow through the respiratory tubal system. It would therefore appear that the organism demands for its psychic comfort the preservation of an equilibrium which has to do with the speed of pulmonary ventilation independent of gaseous exchange.

The preventive and therapeutic action of positive pressure respiration in acute edema, in man and in animals, illustrates again the importance of mechanical or physical factors in the physiology of respiration. Whether or not the pulmonary capillaries filter serum through them into the alveolar spaces is dependent on the internal capillary pressure and the permeability of the vessel wall. An increase in internal capillary blood pressure of sufficient extent to cause edema in the alveoli may be compensated for by the application of an opposing pressure on the external capillary wall. A positive pressure of two to four mm Hg may be sufficient to achieve this object. These pressures may prolong the circulation time of blood through the lungs to a slight extent, but do not seriously interfere with the maintenance of an adequate circulation. It seems probable that the therapeutic use of positive pressure will be of value not only in the treatment of pulmonary edema but also in certain related conditions characterized by pulmonary congestion and it seems also altogether likely that non-arterial pulmonary hemorrhage may be controlled in some instances.

Inhalational therapy has gone within the past two decades from a more or less uncontrolled haphazard administration of oxygen employed generally as a measure of last resort to a specialty of medicine which has as its purpose the management of functional disturbances in respiration. The future of this branch of medicine depends upon the recognition that the pathological physiology of clinical disorders in breathing should be given the fullest study in the individual case. The practice of relegating oxygen therapy to technicians or to nurses tends to defeat this aim. Our purpose in this paper is to present the widening field of inhalational therapy as a subject properly of interest to the clinician and no longer one that is justifiably segregated

Fig 4 Helium oxygen water bottle.

within the province of the physiologist on the one hand or the technician on the other.

Summary

The physiological basis and the clinical results of oxygen therapy in pneumonia, congestive heart failure, acute coronary thrombosis, and pulmonary emphysema and fibrosis have been reviewed. More recent observations on the use of helium with oxygen in asthma and obstructive conditions of the respiratory tract are presented. Mention is made of the addition of positive pressure to inhalational therapy, particularly in the treatment of edema of the lungs and obstructive dyspnea.

The methods employed in inhalational therapy are discussed and a detailed account given of the newer procedures involved in helium oxygen therapy, oxygen therapy, and positive pressure respiration.

The application of physiological studies of respiration to the practice of clinical

medicine is discussed. It has become increasingly important for the clinician to view the pathological physiology of disorders of the heart and lungs from the standpoint of disturbance in their function as well as morphology. In order that the patient may receive physi-

ologically as well as etiologically directed therapy, it would seem justifiable to ask that this branch of medicine be neither segregated with the province of the physiologist, in theory, or restricted to the technician or nurse, in practice.

MUSCULAR DYSTROPHY

Report of a Family

DAVID I ARBUSE, M D and DAVID SLOANE, M D, *New York City*

From the Orthopedic Service of Dr Herman Frauenthal and the Neurologic Service of Dr Charles Rosenheck, Hospital for Joint Diseases

The subject of muscular dystrophy is of neurologic interest, because of the insidiousness of the onset with motor manifestations, the indefinite etiology, the progressive nature, pathology, clinical course, and the chronicity of the disease. Furthermore it is one of the very few organic conditions which show a marked heredofamilial tendency.

In 1830, Charles Bell¹ described progressive muscular atrophy. Semma in 1834 and Costa and Gioga in 1836, recognized and described the syndrome, now known as progressive muscular dystrophy. In 1849, Aran and Duchenne described the fatty pseudohypertrophies and placed this condition as a nosological entity. Duchenne,² in 1868, believed this to be a disease primarily of the muscles, and called it a myosclerosis. Cruveilhier thought the pathology of the disease was primarily in the spinal cord, and Charcot agreed with him. Erb,³ in 1883, suggested the name *Dystrophia Musculorum Progressiva*, and declared that there were two distinct types of progressive muscular atrophy, a spinal atrophic form, and a muscular dystrophic form, differing greatly in localization, syndrome, and evolution. Landouzy and Dejerine,⁴ in 1885, described a form, known as the *Facio-Scapulo-Humeral* type. The two latter types begin with and preponderantly involve the muscles of the shoulder and upper arm, and to a lesser extent the face. The forms which affect the muscles of the pelvic girdle and thigh are atrophic (*Leyden-Moebius*) and the pseudohypertrophies (*Duchenne-Griesinger*). There is some controversy as to whether the Charcot Marie-Tooth type of peroneal atrophy, is a true primary myopathy. Gowers⁵ and Spiller also described a distal type. Most of these types are not sharply demarcated, but overlap, and so we find transitional as well as mixed forms.

Etiology

This disease may occur sporadically or in families.⁶ Voshell,⁷ in 1933, after reporting twenty cases of progressive pseudohypertrophic muscular dystrophy, stated that the age of onset is between two and eight years, with the average at four, and he was of the belief that only the white race is affected. At this time, one of us (A) has under treatment an eleven year old colored school girl, who not only has the classic objective findings of this disease, but very definitely shows polyglandular involvement in general and hyperpituitarism in particular. Pearson⁸ has also described this condition in negro children.

Infectious diseases, overexertion, and trauma may be contributing causes or bring the patient's attention to his motor difficulty. Or, after a temporary arrest of the condition, these factors may cause further progression in the atrophies and pseudohypertrophic muscles.

Endocrine

Changes in the pineal gland producing shadows in roentgenograms, naturally suggested that the disease is due to a disturbance in the internal secretions of the endocrine system. Janney, Goodhart, and Isaacson¹¹ sought to establish a causal relationship between the endocrine dyscrasias and progressive muscular dystrophy. In their investigation, they found changes indicative of endocrinopathology, such as dryness and abnormal pigmentation of the skin, acromegalic features, brittleness of the hair, hypertrichosis, trophic changes in the nails, unusual distribution of the subcutaneous fat, regressive osseous changes, marked retardation of growth, hypoglycemia, delayed glucose utilization, and alterations in the creatin and creatinin output.

in the urine Brock and Kay¹² also found evidence of pluriglandular involvement in their study of this disease

Chemistry

McCrudden,^{9 10} after blood chemistry studies in progressive muscular dystrophy, concludes that the myasthenia is due to a hypoglycemia, that the hypoglycemia and fatty infiltrations are due to impaired glycogenesis, the carbohydrate of the food being probably changed largely to fat instead of glycogen, and that this impaired glycogenesis is the result of adrenal and other endocrine disease

Nevin¹³ studied the chemistry of the skeletal muscles in pseudohypertrophic muscular dystrophy and found low total acid-soluble phosphorus, low creatine phosphoric acid content of resting muscle, and less than normal break down of this substance on stimulation. He considered this alteration as secondary to the muscular degeneration. With reference to muscle metabolism, Tripoli and Beard¹⁴ are of the opinion that in patients with muscular dystrophy, not enough protein is ingested and that which is taken in is not utilized sufficiently. Further, that there is some dysfunction of protein digestion which prevents proper utilization necessary for muscular functions

Heredity

The most likely and most important cause of this malady is probably rooted in the anlage, as shown by the heredo-familial occurrence. The disease is transmitted mainly through the mother to the next generation, although the mother may escape the affliction. Gowers,¹⁵ who reported 118 cases in thirty-nine families, claimed that the pseudohypertrophic type was always transmitted only through the mother, and especially so if it begins early in life. If the disease starts late in life, it can be transmitted by the father or mother. Boys are more often affected than girls (Gowers and others). Weitz¹⁶ reported thirty-five families, in which ninety-four cases occurred. Of these seventy-two were males and twenty-two females. 101 were healthy and free of any muscular involvement. He observed that in the directly

inherited cases, the disease is less severe than in the sporadic or isolated cases. He concluded that the inheritance takes place either in the dominant, simple recessive or sex-linked recessive form, and that many cases can be explained on the theory that new mutations have occurred. De Lisi,¹⁷ after a study of the Charcot-Marie-Tooth type, believed that this condition is transmitted in all forms, namely dominant, simple recessive, and sex-linked recessive. Robinson¹⁸ reported a family of five generations, from 1849-1925, and the records of the 128 children. Of these sixty-five were boys and sixty-three girls. The myopathy affected the shoulder girdle muscles almost exclusively. Neither the face nor lower extremities were involved. The children were sound at birth and during childhood. The age of onset was puberty, and a little earlier in the girls than in the boys.

Diehl, Hansen, and Ubisch¹⁹ believe that the disease is often transmitted by a healthy mother. Niwa,²⁰ in a study of three dystrophic families, found that in the Landouzy-Dejerine type, the transmission was direct through males and females, and indirect in the pseudohypertrophic type. This is in agreement with the findings of Davidenkow and Kryschowa,²¹ Eulenberg and Cohn.²² Barnes²³ is in accord with the evidence which shows that muscular dystrophy is determined at the birth of the ovum, and is derived as a factor or as factors inherited from one or both of the two gametes which form the zygote. In rare cases a new mutation may arise and be the cause of the condition in the individual developed from that zygote, and be transmitted to his descendants. He further believes that in those cases where bacterial infection, trauma, overwork, etc. are antecedent in the history, they are merely factors which determine the onset or accelerate the progress of the disease in an individual who is a potential myopathic. In other words, a genotype carrying the mutant gene or genes, and that apart from such underlying factors, it is probable that the muscular dystrophy can never arise. Kostakow²⁴ studied three generations of a family, comprising fifty-five persons. Forty-seven are living. Of these, twenty-seven are women

and twenty men. Fifteen developed muscular dystrophy, these were exclusively males. If the disease was inherited as a dominant character, transmission must have been from one of the parents directly to about one-half of the children, but this was not the case. Neither of the known original progenitors had the disease. The females acted only as transmitters. There were six females in the first generation and all transmitted the disease to eight of their male children. The seven females of the second generation transmitted the disease to six out of eight males of the third generation. No tendency for the disease to progress in severity in passing from one generation to the next, was observed. The children of the males who were healthy did not develop the disease in any of the three generations. This mode of inheritance is a sex-linked recessive type. It would seem, therefore, that it is much more dangerous for a healthy woman of a dystrophic family to marry, than for a man with the affliction.

Pathology

While Holmes,²⁵ Gil,²⁶ and other investigators, have described alterations in the anterior and lateral horn cells of the spinal cord, Erb, Duchenne, and Friedreich demonstrated definite pathologic localization within the affected muscle tissue *per se*. The lesions are essentially the same, no matter what the type. Microscopically, there is a hypertrophy and atrophy of the muscle fibers. The hypertrophy is the first stage and the atrophy the last stage. The individual muscle fibers waste. They become round instead of polygonal and eventually disappear, leaving the sarcolemma sheath and greatly increased nuclei. Finally, the muscle fibers disappear entirely and are replaced by fat and fibrous tissue. Many of the muscle fibers show fragmentation with an increase in the number of nuclei, other fibers show vacuolization. The striped formation of the muscle is preserved. The muscle degenerates in an irregular fashion i.e. atrophy, hypertrophy or pseudohypertrophy may occur simultaneously in the different parts of the same muscle. It is not inflammatory, but involves one bundle after the other. The

tendon reflex is diminished as the muscle volume diminishes, and in the later stages when the muscle is gone, the reflex is absent. As the muscle atrophies the tone in it diminishes. Motion is not lost completely, unless the entire muscle is gone. The power in the affected muscles is not proportional to the size of the muscle. In the pseudohypertrophic muscles, we note excessive interstitial fatty infiltrations.

It is of more than passing interest to ponder the reason for this disease affecting the trunkal muscles. The primary myopathies usually involve the red muscles, and they are found mostly near the trunk. Further, muscular dystrophy is primarily a disease of the sarcoplasmatic portion of the muscles, or that part which is innervated by the sympathetic nervous system. The fibrillar part of the muscle is innervated through the anterior horn cells.

The muscles usually affected in the Erb type, are the pectoralis major and minor, latissimus dorsi, serratus anticus, rhomboideus, trapezius, deltoid, biceps, triceps, and subscapularis. Less frequently involved are the sternocleidomastoid, infraspinatus, supraspinatus, levator scapulae, and coracobrachialis.

Friedman²⁷ described a case, portraying a combination of primary myopathy of the Erb type with progressive muscular atrophy of the Werdnig-Hoffman type. Steinberg²⁸ reported a case of progressive muscular dystrophy with a marked atrophy of both pectoralis major muscles.

Diagnosis

In any type, if the dystrophy is marked, it cannot be mistaken. Early, the Erb type presents a diagnostic problem. There are congenital cases of atrophy in the muscles of one shoulder, but seldom is it bilateral. Paralysis of the long thoracic nerve will involve the serratus magnus muscle and cause a winged scapula. This condition is usually due to trauma to the nerve, and is especially seen in porters, soldiers, and laborers. Sometimes it is a neuritic paralysis with pain in the shoulder. Sometimes no etiology is apparent. At other times we note this malady after an acute infectious disease, especially after typhoid, acute rheumatic

disease, and gonorrhea. The Landouzy-Dejerine type may be mistaken for the Erb and vice versa. However, the Landouzy-Dejerine variety usually is seen in early childhood, between thirteen and thirty-five, and commences in the face and spreads somewhat more rapidly to the muscles of the shoulder girdle and the upper arm. The patient has difficulty in whistling, speaking, and drinking. The lips are thin and the upper one projects, the so-called tapir mouth. When smiling the mouth elongates, but its corners are not raised (*risus sardonius*). Speech may be greatly interfered with but the muscles of mastication and deglutition are not affected. This serves to differentiate the disease from bulbar paralysis. Later, the atrophy extends to the shoulders and arms, but does not as a rule involve the supraspinatus, infraspinatus or the flexors of the hand or forearm. In the Erb type, the face muscles are not involved until late in the disease, if at all. Whatever groups of muscles may be the first affected, the differences are of degree and of type rather than of kind.

Course

The earlier the onset of the disease, the more rapid is the course.⁸⁰ The apparent halt or arrest of the pathologic

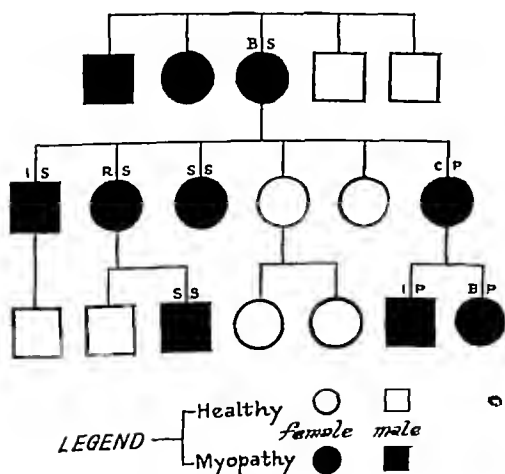

Fig 1 Genealogy of family as far as we have been able to ascertain it. The circles represent females and the squares, males. Those who showed no evidence of muscle involvement, by examination or from the history, are represented by blank squares or circles.

process in the muscles affected may occur for ten, fifteen, or thirty years, but the course is almost always progressive nonetheless. They usually die of intercurrent disease. Muscular dystrophy may be associated with hysteria, mental weakness, epilepsy, and congenital anomalies of bony structures.

Family Record

The records given here consist not only of history and objective findings of our own, but also include information supplied by members of the family concerning their parents and relatives, who are either deceased or who could not be contacted for examination. We have reason to believe that our informants are intelligent and reliable. In the main, for brevity, only positive findings are recorded. They were all of the Hebrew race and white.

B S, the maternal grandmother of our original case, was one of five children, who had an atrophy of the shoulder girdle muscles. She died of an intercurrent disease at the age of thirty-nine. This woman had a brother, whose lower extremities were atrophied to the extent that he could not walk and was bedridden for years, previous to his demise at the age of forty-four. Another sister was also unable to walk, due to involvement of the lower extremities. She died at the age of forty-two.

S S (Fig 2), a sixteen year old high school student, and the oldest of two children, first presented himself in the outpatient department of the Hospital for Joint Diseases on September 5, 1935, complaining of a weakness of both arms, of three years duration. He noted a progressive weakness, especially when attempting to raise both arms to the shoulder level. Also he was aware of the fact that his back became more prominent and his coat did not seem to fit as well as it formerly did. Examination revealed a well-nourished and developed boy, rather large for his age. Both shoulders drooped and there was a prominence of the scapular angles. When the patient was asked to abduct both arms or to extend them forward at shoulder level, both scapulae became winged. There was a definite atrophy of the shoulder muscles bilaterally, but more marked on the right. When the scapulae were held against the back, the patient was able to

Fig 2 and 3

the arms almost to the normal upright position. The biceps and triceps jerk were not elicited. Electrical examination of the muscles of the shoulder girdle showed a fair response to faradic stimulation in both trapezi deltoidei and pectoral muscles, and a very poor response to galvanic stimulation in the rhomboids bilaterally, and a very poor response in the right subscapularis and none on the left. The general electrical examination was negative with the exception of early greying of his hair

and a brown-stained pigmentation of the skin on the face and back. X-ray of the spine showed a habituated transverse process of the seventh cervical vertebra on the right side.

R. S. (Fig 3) a thirty-one year old housewife and mother of S. S. first observed the condition when she was eight years old, although obviously the disease must have existed for several years prior. At ten or eleven years of age she noticed that her father was turning grey, and that when he reached her

disease, and gonorrhea. The Landouzy-Dejerine type may be mistaken for the Erb and vice versa. However, the Landouzy-Dejerine variety usually is seen in early childhood, between thirteen and thirty-five, and commences in the face and spreads somewhat more rapidly to the muscles of the shoulder girdle and the upper arm. The patient has difficulty in whistling, speaking, and drinking. The lips are thin and the upper one projects, the so-called tapir mouth. When smiling the mouth elongates, but its corners are not raised (risus sardonicus). Speech may be greatly interfered with but the muscles of mastication and deglutition are not affected. This serves to differentiate the disease from bulbar paralysis. Later, the atrophy extends to the shoulders and arms, but does not as a rule involve the supraspinatus, infraspinatus or the flexors of the hand or forearm. In the Erb type, the face muscles are not involved until late in the disease, if at all. Whatever groups of muscles may be the first affected, the differences are of degree and of type rather than of kind.

Course

The earlier the onset of the disease, the more rapid is the course.³⁰ The apparent halt or arrest of the pathologic

process in the muscles affected may occur for ten, fifteen, or thirty years, but the course is almost always progressive nonetheless. They usually die of intercurrent disease. Muscular dystrophy may be associated with hysteria, mental weakness, epilepsy, and congenital anomalies of bony structures.

Family Record

The records given here consist not only of history and objective findings of our own, but also include information supplied by members of the family concerning their parents and relatives, who are either deceased or who could not be contacted for examination. We have reason to believe that our informants are intelligent and reliable. In the main, for brevity, only positive findings are recorded. They were all of the Hebrew race and white.

B S, the maternal grandmother of our original case, was one of five children, who had an atrophy of the shoulder girdle muscles. She died of an intercurrent disease at the age of thirty-nine. This woman had a brother, whose lower extremities were atrophied to the extent that he could not walk and was bedridden for years, previous to his demise at the age of forty-four. Another sister was also unable to walk, due to involvement of the lower extremities. She died at the age of forty-two.

S S (Fig 2), a sixteen year old high school student, and the oldest of two children, first presented himself in the outpatient department of the Hospital for Joint Diseases on September 5, 1935, complaining of a weakness of both arms, of three years duration. He noted a progressive weakness, especially when attempting to raise both arms to the shoulder level. Also he was aware of the fact that his back became more prominent and his coat did not seem to fit as well as it formerly did. Examination revealed a well-nourished and developed boy, rather large for his age. Both shoulders drooped and there was a prominence of the scapular angles. When the patient was asked to abduct both arms or to extend them forward at shoulder level, both scapulae became winged. There was a definite atrophy of the shoulder muscles bilaterally, but more marked on the right. When the scapulae were held against the back, the patient was able to

Fig 4 and 5

two decades of life, and was hardly noticed in the beginning. The first symptoms of muscular impairment, both in size and power, occurred at the axioap-
pendicular junction. There has been little progression of the affliction to date. The atrophied and pseudohypertrophied muscles were not quite symmetrically involved, and produced a bizarre appearance of the contour of the neck and shoulders, and the contour of the patient's body was distorted in outline. The

atrophic and pseudohypertrophic muscles adjoined well-formed portions of the limbs. None of the cases with shoulder involvement had any difficulty in arising from a prone posture and there was no suggestion of "climbing up" on themselves.

We observed local disfigurement, such as winged scapulae. This is due to the elimination of the serratus muscle action with abnormal mobility of the shoulder blades. If to this is added, that of the

right arm, it would fall limp at her side. As she grew older it was difficult for her to comb her hair or to raise any object to her mouth. In order to put on her hat, she had to rest her elbow on a table for sustained support. Examination showed a well-nourished and developed female with the typical weakness and atrophy of the muscles in the shoulder girdle, more marked on the right, with the consequent greater winging of the right scapula. Because of the atrophy and pseudohypertrophy in the muscles, her neck and shoulders are abnormally wide. Her spine was slightly scoliotic. Electrical examination revealed only a quantitative reduction of response to faradic and galvanic stimulation of the muscles undergoing atrophic changes.

S S, (Fig 4) age twenty-nine, a Russian born art teacher, and maternal aunt of S S the original case, first noted a weakness in both arms at the age of eleven, and a weakness of the right side of her face at thirteen. She gave a history of having had spinal meningitis at the age of one. At twenty, she was told that she is "asymmetrical in her structure," because she could not be fitted with a vaginal pessary. She was pregnant four times, but has no living children. Six years ago, she was delivered by cesarean section of a dead baby. Examination revealed a poorly nourished and underdeveloped female. Asymmetry of the right face, with a difficulty in blowing out of the cheeks especially on the right. Whistling and pouting of the lips was also difficult. There was a marked deepening of both supraclavicular spaces with slight winging of both scapulae. The right shoulder and hip are slightly higher than the left. The skin of the face, chest, and back showed a brownish freckling, more marked than the other cases. This case is one of the Landouzy-Dejerine type of dystrophy.

I S, (Fig 5) age thirty-two, an uncle of S S, and a dress cutter by trade, first noticed a weakness of the right arm at the age of twenty. At this time it was brought to his attention, when he went to buy a ready-made suit. The tailor told him, he would have to have a coat made to order, "because his bones protruded in the back and that the right shoulder is lower than the left." Examination revealed a well-nourished and developed male with a left facial asymmetry and weakness. Atrophy and weakness of the muscles of the right arm, with inability to extend it at the shoulder level, but able to raise the arm perpendicularly. Both scapulae were

winged, but more so on the right. The neck appears wider. A slight scoliosis of the spine was apparent. This case too, should be classed as among the Facio-Scapulo-Humeral type of myopathy (Landouzy-Dejerine).

C P, age thirty-nine, another sister, and maternal aunt of our original patient S S, merely showed a weakness in abduction of the left arm, as it approached a ninety degree angle. With the use of accessory muscles, she could overcome this difficulty, and elevate her arm to the normal vertical range. She stated that she had this weakness as far back as she could remember.

B P, age twenty-two, a daughter of C P, and first cousin of the original patient S S, complained of a weakness of the left leg with a tendency to stumble while walking. At about thirteen years of age, she became aware that her left leg was thinner than the right. This has progressed, especially in the last four years. She was told that she has been sleeping with her eyes open during the past eight years.

Examination revealed a myopathic facies. Her gait was somewhat steppage on the left, due to a weakness of the left peroneal and tibialis anticus muscles, with difficulty in dorsiflexion of the left foot. There was also an atrophy of the muscles of the left leg, and to a much lesser degree in the left thigh muscles. The left Achilles jerk was not elicited. The right ankle as well as both knee jerks were present and active. The electrical responses were quantitatively reduced in the muscles of the left lower extremity. She showed no involvement of the shoulder girdle muscles. A pilonidal cyst in the sacrococcygeal region was noted.

I P, age twenty, a medical student, son of C P and brother of B P, communicated with us and volunteered the information that he had a mild involvement of the muscles of the shoulder girdle bilaterally, with a slight winging of the scapulae. Three years ago he was operated for a pilonidal cyst. He, too, was told that he sleeps with his eyes open. He was unable to present himself for examination.

Comment

We are reporting a family, showing typical dystrophic manifestations especially in the shoulder girdle muscles. In some, the dystrophy involved the face and in others, the lower extremities. The onset in all of them was within the first

ACUTE INFLAMMATION OF THE GALL-BLADDER AND BILIARY DUCTS

JOHN DOUGLAS, M.D., *New York City*

The purpose of this presentation is to facilitate the diagnosis of pathological conditions, and to determine what should be done when diagnosis is made. As acute inflammation may develop from chronic conditions, the latter must also be considered with the idea of prevention of the occurrence of acute attacks. For the purpose of diagnosis, it is essential that the etiology and pathology be studied.

Three main factors determine the development of gall-bladder disease—infection, biliary stasis, and cholesterol metabolism. The anatomy of the gall-bladder with its narrow opening into the tortuous cystic duct, its lymphatic drainage into the regional nodes about the ducts, the lymphatic connection between the liver and the gall-bladder, its main blood supply by means of the single cystic artery, and impaired physiological functions of the liver, are all contributing factors in the pathological conditions which may develop. It has also been suggested that beside bacterial infection, a biochemical factor may be the cause of an acute lesion.

Infection may reach the gall-bladder or ducts by means of the blood stream, lymphatic channels or through the ducts from the duodenum. The latter source of infection is probably the least important, although Ivy proved that in animals in which the sphincter of Oddi had been destroyed, infection is apt to enter the ducts. Colp has reported that in certain cases of cholecystitis, pancreatic ferments may be obtained from the gall-bladder, which have evidently entered by a reflux from the pancreatic duct. As opposed to this however, the bile from the chronically inflamed gall-bladder is frequently found to be sterile, while pathogenic organisms may be grown from cultures of the gall-bladder wall. It is also known that after reconstruction of the common bile duct, particularly by the

different implantation methods, cholangitis is apt to follow and persist.

The method of infection through the lymphatic channels is also controversial. It has been stated that infection from a duodenal ulcer, an inflamed appendix or other abdominal inflammatory lesions, may result in gall-bladder infection by means of the lymphatic channels. In the presence of an inflamed gall-bladder, it is a frequent observation to find a contiguous area of the liver which shows an inflammatory area, and it has been assumed that this liver infection is due to an infection spreading through the gall-bladder by means of its rich lymphatic connections to the liver. On the contrary, it is known that the liver has a detoxicating power not only chemically but also bacteriologically, it is the belief of Graham and others, that the infection may spread from the liver to the gall-bladder. In a study of some two thousand cases, recently made by Shelly of St. Luke's Hospital, [New York City] the results of which have not as yet been published, in which the appendix was removed in the course of operation for some other abdominal lesion, a pathological condition of the appendix was found less frequently in those cases where the primary operation was performed for gall-bladder disease or duodenal ulcer, than in those in which it was removed incidentally in an operation for uterine fibroid or ovarian cyst, or some other non-inflammatory lesion. This, while not being in any way conclusive, would appear to be of some negative value.

It is probable however, that the main source of infection of the gall-bladder, particularly in acute cholecystitis, is by means of the blood stream and while the infection may be through the portal system at least in acute gall-bladder disease, the infection spreads more frequently through the general circulation. In a

pectoralis, trapezius, and latissimus dorsi, the shoulder blades, with the attached arms, become loose appendages of the thorax, the so-called "Loose shoulder." The arms seem much longer, when they are stretched out. Through involvement of the orbicularis muscles of the eyes and mouth, the myopathic facies is produced. The atrophy of the trunk muscles can lead to the "wasp waist."

The organic reflexes and sphincteric control were intact. No sensory disturbances were elicited. No motor paralysis was noted, except such as would result, secondarily, from the pathology in the affected muscles. The apparently hypertrophied muscles were weak. The tendon reflexes were diminished or ab-

sent, depending on the extent of the muscular impairment. No fibrillary contractions of the muscles were noted in our cases, but Spiller²⁹ has observed this phenomenon in true dystrophy. In those cases, where tests were made, the electrical responses were quantitatively, but not qualitatively, reduced.

Summary

We herewith presented a dystrophic family, demonstrating clinically, (1) the hereditary character of the disease, (2) early onset, and (3) relative limitation of type.

THE WAR ON SYPHILIS

The United States Public Health Service is cooperating with the New York City Department of Health in an effort to improve and facilitate the reporting by private physicians and hospitals of cases of syphilis and gonorrhea occurring in their practice. In order to simplify this procedure a new form will be used hereafter, giving accurate and complete information concerning each patient. Cases may be reported by initial but for statistical reasons it is preferable that the full name should be used whenever possible. Physicians' reports are kept absolutely confidential.

To private physicians the New York City Department of Health offers diagnostic laboratory services and diagnostic and therapeutic consultation for patients who

are not able to pay the usual fee for these services. In addition the United States Public Health Service in cooperation with the Department of Health is now supplying drugs upon the request of private practitioners for the treatment of early syphilis, syphilis in pregnancy and congenital syphilis.

The Department of Health and the United States Public Health Service wish to cooperate with the physician in finding sources of infection and in bringing the family and other contacts to him for examination, and in keeping patients under treatment at least until noninfectious. No effort will be made to investigate any patient unless specific request is made by the physician.

Pathological conditions found at operation for acute or chronic cholecystitis will differ depending on the etiological factors present. There may be a thin-walled acutely distended gall-bladder, which may or may not contain stones but in which there is only a moderate amount of inflammation of the gall-bladder wall. In the type of inflammation occurring in repeated mild attacks, the gall-bladder wall may be markedly thickened, or in cases where the stone has left the gall-bladder and entered the common duct, the gall-bladder may be contracted down to a size smaller than the original stone. Occasionally, a large stone will ulcerate through the gall-bladder into the duodenum, other portions of the intestinal canal or even into the peritoneal cavity, the opening closing up leaving a small contracted gall-bladder. In such a case, a stone large enough to block the small intestine may pass on until it stops somewhere and causes an acute intestinal obstruction. The acutely inflamed gall-bladder associated with gall-stone is frequently associated with some virulent type of infection. It becomes markedly inflamed and swollen, and if examined in this stage, one will often find a stone in the ampulla blocking the cystic duct, and the gall-bladder filled with stones and infectious bile or even pus. Its mucous membrane is red or even ulcerated, the wall edematous and infiltrated with round cells and leukocytes. The serosa is red and injected and covered with lymph and beginning to become adherent to the contiguous colon, omentum, duodenum, and liver. Such an inflammation may subside if the gall-bladder empties itself by displacement of the stone in the ampulla, symptoms of chronic cholecystitis may persist or an acute attack may recur. On the other hand this inflammation may continue and result in perforation of the gall-bladder, or the impaired circulation results in gangrene of the gall-bladder wall with surrounding abscesses or the development of a subphrenic abscess or even a spreading peritonitis.

Obviously the symptomatology will depend upon the pathological condition and its subsequent development. The symptoms of a typical classical case of acute cholecystitis will be in a patient, more

frequently a woman, often one that has borne children, in the fifth decade of life, who may or may not give a history of a previous attack or symptoms suggesting chronic disease of the gall-bladder. The attack will begin with epigastric distress soon followed by inspiratory distress, right upper quadrant pain, and vomiting. The pain is frequently referred to the right scapular region and is often agonizing in character. As the inflammatory condition develops, there is elevation of the pulse rate and temperature, and an increase in the total leukocyte count with a polymorphonuclear leukocytosis. There is local tenderness in the right upper quadrant with an increased rigidity in this region, and as the gall-bladder becomes enlarged, and if the muscular rigidity is not too great, a mass may be felt. With the further development of the disease, if some cholangitis occurs, an icteric staining of the sclera may be evidenced. In the presence of such a group of symptoms particularly with a history of previous attacks, the diagnosis is easy.

But, unfortunately we do not always have to deal with such a typical group of signs and symptoms. The pain in the beginning of the attack may not be referred to the back or located in the right upper quadrant, but is referred to the epigastric region or to the left upper quadrant. In many cases there may not be very much elevation of the temperature and in a considerable number of instances—in fact, in almost one-half of the cases—the leukocyte count at first, may be within normal limits, while the pathological lesion in the gall-bladder is out of all proportion to the temperature or blood count. The late Dr Judd cited seven cases from the Mayo Clinic, in which a general abdominal infection developed while the patients were under observation and stated that in none of these cases was it possible to recognize gall-bladder pathology from the symptoms and it was not even suspected that rupture of the gall-bladder was the cause of the symptoms until autopsy was performed. He also cited eighteen autopsy cases in which evidence of acute cholecystic disease was found, and although the condition of the gall-bladder was not responsible for the death of the patient,

series of thirty-one cases of acute non-calculus cholecystitis reported by Wolfson and Rothenberg, nine gave a definite history of extra-biliary infection preceding the cholecystitis.

More than ninety per cent of the cases of acute cholecystitis are associated with calculi in the gall-bladder. Wolfson and Rothenberg have collected from various sources as well as from their own cases, over twelve hundred cases of acute gall-bladder disease in which 81 per cent showed no stones present. They called attention to the fact that in their own series, the condition was more frequent in men than in women although gall-stones formed more frequently in women than in men.

As gall-stones are found to be such an important factor in acute disease of the gall-bladder, the cause of gall-stones must be considered. Various factors here are of influence, cholesterol being the main constituent of gall-stones. Impaired cholesterol metabolism results in the precipitation of cholesterol with the formation of gall-stones. This change in cholesterol metabolism particularly occurs in pregnancy, and during high fever. Its occurrence during pregnancy is one of the reasons for the occurrence of gall-stones in women during the child-bearing period. During fever and pregnancy more cholesterol is formed and held in solution. With subsidence of temperature and after pregnancy, the excess cholesterol may be precipitated. Thus, there may be found at times an almost pure white single cholesterol stone, or what is called a typical strawberry gall-bladder may be observed in which small cholesterol crystals are found in the folds of the gall-bladder mucosa. Stagnation of bile in the gall-bladder, or impaired liver function, lessening the amount of bile salts which keeps cholesterol in solution, also is a contributing factor. In addition to this, infection when it occurs results in calcium precipitation and with these various factors at work, gall-stones are built up.

Gall-stones may be formed of pure cholesterol or contain from twenty to ninety per cent cholesterol with calcium carbonate, calcium phosphate or calcium bilirubinate. Occasionally are found small blackish or greenish stones formed

only of bilirubin or its calcium salt. Calcium carbonate or phosphate may be the sole constituent of stones in three per cent of the cases. While it has been generally believed that the Liesegang rings shown by cutting across a gall-stone are evidence of its gradual formation, there is much evidence to confirm the view of Sweet, that one large stone may be formed by precipitation and crystalization. The rings are formed by rhythmic precipitation of calcium bilirubinate throughout a colloidal cholesterol mass.

Once a stone or stones are contained in the gall-bladder their contributing influence in the development of an acute or chronic cholecystitis becomes obvious. By their presence as a foreign body causing chronic irritation, they may impair the function of the gall-bladder by causing sufficient irritation, or erosion of the gall-bladder wall allowing entrance of bacteria, or a stone in the ampulla may act as a ball valve closing off the opening of the cystic duct and preventing the gall-bladder from emptying and thus causing an acute distention of that organ or even empyema of the gall-bladder. Furthermore a stone impacted in the gall-bladder or cystic duct may by mechanical pressure interfere with the circulation in the gall-bladder wall, first by interfering with the venous return, resulting in the congested turgid edematous organ seen in an early acute cholecystitis, later by arterial compression, and thrombosis and ischemia resulting in gangrene of certain areas and perforation, or gangrene of the whole organ.

We also must recognize the fact that so-called silent gall-stones exist. Truesdell of New York, has kept a careful record of the examinations of the gall-bladder in patients on whom he has done pelvic operations, and found incidental gall-stones in forty-four out of 462 cases or 9.5 per cent, in none of which had been made a preoperative diagnosis of disease of the gall-bladder. While careful questioning postoperatively elicited some gall-bladder history in a considerable number of cases, no suggestion of gall-stones or cholecystitis could be elicited in others beyond some digestive disturbances which frequently were indefinite.

frequently compelled after careful examination and evaluation of all the signs and symptoms to make a diagnosis, of probability, instead of being positive of our preoperative diagnosis. An acute inflammation of the appendix which is located high in the abdomen rather than in its usual position may also present difficulty of differentiation and while perforation of the gall-bladder, because of its anatomical situation is usually walled off and the inflammation confined to the upper quadrant, a general peritonitis has occurred. As in the cases cited by Judd, the fact that the primary lesion was in the gall-bladder may be impossible to determine. Co-existing disease of the right kidney and gall-bladder also calls for careful study to determine the cause of symptoms then present.

The variability of signs associated with acute cholecystic disease also applies to stone in the common duct. The symptomatology of the classical case associated with cholangitis may present little difficulty in diagnosis. A typical gall-stone colic with pain referred to the right scapular region, jaundice, chills, and the septic type of temperature associated with the name of Charcot, form a chain of symptoms which present little difficulty of diagnosis. But when it is recognized that ten per cent of the cases of common duct stone may have no jaundice, almost one-third occur without chills or fever, and that common duct stone may occur without pain, the difficulty of diagnosis here becomes apparent.

In the opening paragraph of this contribution it was stated, that acute inflammation of the gall-bladder may develop upon chronic pathological conditions. As the latter is not the subject under consideration, it therefore must be considered briefly. Chronic gall-bladder disease may have as symptoms, an evidence of indigestion, particularly an intolerance for fatty foods, belching of gas, abdominal distention, and pain or at least discomfort in the epigastric or right hypochondriac regions. When this occurs in a woman who has had children, most frequently in the fifth decade of life, gall-stones or cholecystitis may be suspected. If there had been a history of subacute or acute attacks of more severe pain which has been referred in the region

of the right scapular, with tenderness under the right costal margin, for a day or so after the acute attack has subsided, the diagnosis is still more probable. If these attacks are accompanied by slight jaundice, we have further evidence of chronic gall-bladder disease with an acute or subacute exacerbation. It must be remembered however, that gall-bladder disease while frequent in the fifth decade of life may occur in any age, and in the male as well as the female. If gall-bladder disease is suspected either in the chronic or acute form, a plain x-ray film may show the presence of gall-stones, if the stones contain a sufficient amount of mineral salts to make them cast a shadow. Or the film may show a shadow caused by calcium carbonate incrustation in the wall of the gall-bladder. In a small percentage of cases, calcium carbonate mixed with bile, so concentrated as to form a white grayish mud, may partially or entirely fill the gall-bladder and cause a dense shadow on the x-ray film. As cholesterol is less dense than the gall-bladder wall or even the bile, the stone or stones of pure cholesterol unless containing a sufficient amount of mineral salts will cause no shadow on the film. Therefore a negative plain film is of no value.

Cholecystography, a method devised by Graham depending on the filling of the normal gall-bladder with dye administered by mouth or intravenously and the subsequent emptying of the gall-bladder following a fatty meal, is of the greatest confirmatory diagnostic value in chronic cases. The sodium salt of tetraiodophenolphthalein is usually employed, and is now almost always administered orally, of course this cannot be made use of during an acute attack. If the gall-bladder following the ingestion of the dye, fills normally and empties promptly, it is good evidence of normal functioning, as a diseased gall-bladder does not as a rule function normally. However, it may appear normal in contour and outline and empty promptly after the ingestion of the fatty meal and still contain stones. Frequently stones which do not show in the x-ray film by a plain plate may be demonstrated by the use of dye, because of the contrasting density of the stones and the dye.

the symptoms had been overshadowed by the coexisting disease, or were not present. These instances were cited as examples of the masked or inadequate symptoms accompanying the development of acute gall-bladder disease. It is evident also that a variety of pathological conditions may present the same clinical signs.

Zollinger in 1935, published the results of a number of experiments he had performed to explain the character of the pain and nature of the vomiting in the presence of inflammation and distention of the gall-bladder and ducts. He showed that the epigastric pain which is present in one-third of the cases was caused by distention of the gall-bladder or the ducts and explained this as being visceral in origin. The right epigastric pain occurred with inflammation of the gall-bladder and was due to the stimulation of adjacent cerebrospinal nerves. He was unable to reproduce the pain referred to the right scapular region experimentally. The anatomical explanation of this pain is through impulses, referred to the celiac ganglia of the lower posterior dorsal nerve roots. He also found an absence of vomiting when the gall-bladder was distended, and that the vomiting was a prominent symptom of the distention of the ducts. A series of experiments have also been done within the past year by Dr. Waltman Walters, with Drs. J. M. McGowan and W. L. Butsch of the Surgical Division at the Mayo Clinic, in patients on whom drainage of the common duct had been instituted. By increasing pressure in the common duct, pain could be caused, and it is of particular interest that morphine had little value in relieving this pain, whereas in a number of cases, it had been immediately relieved by inhalation of an amyl nitrite perle, or the introduction of one one-hundredth grain of nitroglycerin under the patient's tongue. The explanation of this phenomenon was that the pain was caused by spasm of the sphincter of Oddi.

The unreliability of the blood count and the temperature elevation has also been alluded to. Perhaps the explanation of this, is the fact that the circulation of the gall-bladder depends on the small artery and vein along the cystic duct, the

general lymphatic drainage following the same course. When there is an early interference with both the circulatory and lymphatic drainage this would limit constitutional absorption, therefore the constitutional reaction is shown by temperature elevation and changes in the blood count. Perhaps another explanation may be that of Dr. Judd, who states that there is evidence that cholecystitis is not always the result of infection, as similar changes in the gall-bladder to those caused by infection, have been produced experimentally by the introduction of certain chemical substances into the blood stream. The foregoing may be some explanation for the variability of symptoms but they do not make it any easier for us to determine the extent of gall-bladder pathology by the signs and symptoms the patient may present. Recognition of this fact is responsible for the general tendency of many surgeons during the past few years to oppose the accepted policy of delay of operation in the acute cases.

While we have seen that in the presence of recognized gall-bladder disease it is difficult to determine just what the pathological condition is, it is also not always possible to determine positively that the symptoms present are caused by gall-bladder disease. Perforation of a duodenal ulcer, an acute pancreatic necrosis, or diseases of the colon or right kidney may present a chain of symptoms closely resembling cholecystic disease. While there are points by which a differential diagnosis may be made in a number of cases, in many instances it cannot be much better than a good guess. In going over a series of operations for acute pancreatic necrosis at St. Luke's Hospital, the common error in diagnosis was to mistake this lesion for acute cholecystitis.

An acute massive perforation of the duodenum accompanied by collapse, the rapid development of rigidity, with air in the peritoneal cavity may not present great difficulty in making a differential diagnosis, on the other hand a slowly developing perforation with localization of the surrounding peritoneal irritation which would extend to the region of the gall-bladder and ducts, may cause the greatest difficulty in differentiating it from cholecystitic disease—and we are

that after the clinical symptoms had largely subsided, the pathological condition might still remain that of an acute inflammation or even progress in severity. It was also apparent that perforation or gangrene of the gall-bladder while not of frequent occurrence, gave a mortality of fifty per cent if the perforation were free into the general peritoneal cavity. Also an operation which has been deferred until dense adhesions had formed about an acutely inflamed gall-bladder is technically more difficult than cholecystectomy in the acute stage. So the conclusion was reached by many surgeons that the danger of delay appeared to be greater than the danger of early operation.

This idea became further crystalized when Miller and Mentzer, in two papers published in 1930, and a second paper by Mentzer, and one by Zininger in 1932, emphasized both logically and statistically the danger of delay. Three papers read by Stone, Judd, and Smith before the American Surgical Association in 1933, while differing somewhat in emphasis on the necessity of promptness of operation, abandoned the teaching of delay in all cases, and in the discussion of their papers, no voice was raised in opposition to this teaching, although there are still some who believe that the postponement of operation until the acute inflammation has subsided, will give a lowered mortality.

To outline definitely a method of procedure which would cover the handling of all cases of acute cholecystitis and which would be acceptable to all surgeons would be impossible. One may however, I believe, outline a plan which is my own method of approach in such conditions, and in which probably a large number of surgeons would concur. It is agreed that all cases with few exceptions should be operated on. The point of controversy is *when*. It is agreed that cholecystectomy unless definitely dangerous is preferable to cholecystostomy. If the symptoms are mild, it is preferable that the patient have the advantage of having preliminary treatment with glucose and saline intravenously, to increase the glycogen reserve of the liver and increase their operative resistance. At the same time, kidney function can be determined, and if jaundice is present to a marked

degree which is usually not the case, unless there is also a common duct-stone or cholangitis, blood transfusions or administration of calcium chloride may be employed to lessen the danger of post-operative hemorrhage.

This means a short delay, but not necessarily until all symptoms have subsided. In the presence of very acute pain and an unusually high leukocyte count, and much temperature, which would indicate imminent or occurring gangrene or perforation, the patient's safety will be better conserved by immediate operation than delay. It must be further borne in mind, as was previously mentioned in determining the plan of treatment, that during this period of delay, the acute pathological process may still be present and progressing with subsidence of the clinical symptoms and laboratory data. It is definitely my belief that enough statistical evidence has now been collected and reported to prove that in a great many cases, delay can cause more mortality and morbidity than is compensated for by any of the arguments in favor of waiting until all symptoms have subsided. Numerous writers have proven this. While very few instances of acute cholecystitis are to be considered in the nature of an imperative emergency as in acute appendicitis, the idea of waiting until all acute inflammation has subsided, I believe is gradually being abandoned and the idea of prompt operation rather than delay or immediate emergency operation accepted.

It is not the purpose of this to go into the technical part of surgical operations, suffice it to say that in the presence of jaundice due to common duct stone or cholangitis, which fortunately (usually) does not occur with acute gall-bladder disease, it is necessary to remove the stone and drain the duct, if the patient is to be relieved of his symptoms.

In order to help us save the lives of more patients on whom operation should be performed, it is necessary to know the causes of death after gall-bladder operations. Heuer has made a study and reported on a thousand gall-bladder and bile duct operations from New York Hospital and of 36,623 from the literature. It is of interest to note how closely these correspond in the most common

That is, negative shadows due to less dense cholesterol stones may be evidenced against the more dense shadows of the dye in the gall-bladder. When after the proper technic of taking the films after the administration of the dye, there is no filling of the gall-bladder and there is no gall-bladder shadow on the x-ray film, this is interpreted in most instances as being caused by a stone either in the cystic duct or in the ampulla blocking the cystic duct and preventing the filling with the dye. While this in the majority of instances may be considered of the utmost diagnostic value, it again must be remembered that in a definite percentage of cases, temporary edema of the cystic duct, perhaps the blocking of the cystic duct by mucus or other causes, may prevent the gall-bladder filling with the dye in the absence of gall-stones. This may result in a wrong diagnosis. It has been my belief that a non-filling gall-bladder, unless demonstrated by a second examination, is not sufficient without good confirmative clinical symptoms to justify operation. It is only fair to state however, that in a consecutive series of 191 operated cases at St. Luke's Hospital, the percentage of preoperative error in diagnosis made by Dr. Eric Ryan by cholecystography was only 4.79 per cent, and that the non-filling gall-bladder furnished one of the smallest percentages of error.

A cholecystogram is also of value to determine when a shadow of a stone has been shown in the right hypochondriac region to differentiate whether the stone is located in the gall-bladder or in the upper pole of the right kidney, and particularly where coincident diseases of both organs may be present. But again, the cholecystograph should not be used if there is jaundice or a suspicion of an acute lesion of the gall-bladder being present. In such cases or as a confirmatory measure, an examination of the fluid obtained by duodenal drainage may be used, the presence of bacteria and crystals, particularly cholesterol and bilirubin crystals being sought.

As this is intended to be of value to the general practitioner, the technical part of the operative treatment of gall-stones and cholangitis should not be considered. However, as patients are under the care of the general practitioner before they

reach the surgeon, the question of when operation should be performed is of the utmost importance to them.

Prior to 1930 to 1932 the general consensus of opinion favored delayed operation in acute gall-bladder disease. Delayed operation was based on the assumption that most of the milder attacks of acute cholecystitis subsided spontaneously, and that the danger of operation during the time of acute inflammation would necessarily cause an increased operative mortality because of less resistance of the patient, and greater danger of spread of infection. It was recognized that in acute appendicitis, if not operated upon promptly, perforation would probably occur with development of general peritonitis. In acute cholecystitis however, not only was it probable that the acute inflammation would subside in mild cases, but also that the inflammatory area would become walled off by adhesions in the presence of more severe inflammation. It was also assumed that perforation rarely occurred, and if it did, the area would be walled off with the formation of a local abscess. Furthermore, patients with acute cholecystitis were usually of an age, or as a result of their gall-bladder disease, apt to have impaired heart, liver or kidney functions which by proper treatment might well be put in a condition to more successfully cope with a major operation. Also the danger of upper respiratory infection had to be considered.

These were a formidable array of reasons for delay, and there was an equally formidable array of surgical authority both here and abroad who advocated postponement of operation until the acute symptoms had subsided, unless there occurred evidence that the pathological condition in the gall-bladder was becoming worse.

In the last few years, there has been a decided change in the opinion of more and more surgeons in favor of earlier operations. It was recognized as previously mentioned when discussing symptoms, that the pathological condition of the gall-bladder might be out of all proportion to the temperature, blood count, and clinical symptoms, that the general symptoms might improve while the pathological condition was progressing, and

which would apparently fall into one of these three classifications. However, it is contended by some surgeons—notably Colp and Turoff—that in a large group of cases dying after gall-bladder operation or from acute gall-bladder or duct disease, when no operation has been performed, an autopsy will nearly always reveal some type of infection, either of the peritoneum and liver, or its ducts, or pulmonary infection which would explain death rather than some chemical condition which would be dependent on altered function of the chemistry of the liver.

The effect of infection by anaerobic organisms has been receiving more attention recently, and probably more positive cultures would be obtained if anaerobic cultures were made.

A careful study of why patients die from certain diseases or following operation for those conditions, should be of the greatest value to avoid mortality and promote their recovery. Knowledge so acquired is helping us in the treatment of acute inflammation of the gall-bladder and bile ducts.

PRESERVE THE AMERICAN MEDICAL

Leading pharmaceutical manufacturers are joining forces with the physicians to resist the threat of state medicine which hangs darkly on the horizon. The Petrolagar Laboratories are sending broadcast a little folder which is made attractive by a reproduction of the famous painting of "The Doctor" by Sir Luke Fildes, and which contains this fine tribute to the work of the family physician under our present American system. It runs:

In our country today the average citizen is still able to select a doctor in whom he has confidence, and who will feel that his duty to his patient is paramount to all other obligations. For some time our doctors have been

concerned over the threat of socialized systems of medicine which would destroy individualism, inhibit initiative, and place the politician between the doctor and the sick who call on him for relief from suffering and the cure of disease. Today the quality of medical service in the United States is better than that available in any other large nation in the world. This record is the result of the application of the individual principle to medical practice and is the chief factor which distinguishes American medical practice from that in many other countries. Our doctors are concerned with giving more and better medical care to all the people. It is an obligation which they have never denied in the past, and which they will be proud to continue under the present system.

TIME TO PARK THE HORSE AND BUGGY

Needless waste of public funds in the fight against tuberculosis was charged to fence-straddling policies of public authorities in an address which Dr Robert E. Plunkett, superintendent of Tuberculosis Hospitals of the State Department of Health, gave on April 11 before the St. Vincent De Paul Society in Troy.

Dr Plunkett declared there is a needless waste of millions of dollars counted in terms of unnecessary deaths, preventable illness and disrupted homes. Open acceptance and advancement of the state's campaign for early diagnosis of tuberculosis was advised as one means of stemming the expensive tide.

"Every 34 minutes a new case of tuberculosis is reported in New York State, but only once in every 170 minutes is a case reported which holds real promise of recovery," Dr Plunkett declared, "In other words, four out of five cases have reached

advanced stages before proper medical care and supervision are provided.

"It is estimated that each case costs society, directly or indirectly, at least \$500. In addition, tuberculosis leaves in its wake the seeds for other cases. It is estimated that in this state, 45,000 persons are suffering from the disease.

"Why do we tolerate tuberculosis? Because too many persons are still living in the horse and buggy days and have not seen fit to retire the horse to pasture and the buggy to a museum and use modern weapons in the control of the disease. The x-ray is one of the most important weapons."

EXAMINE HIS PIPES

Doctor "Have you any organic trouble?"

Patient "I think I have. I can't even carry a tune."

—Colorado Medicine

cause of death in the two lists. Consequences of surgical procedure—peritonitis and shock—are given as thirty-three to thirty-seven per cent. Next in frequency is pulmonary complications which is twenty to twenty-five per cent, cardio-renal complications ten to twelve per cent, liver deaths four per cent, pancreatitis two per cent. In the list there are seventeen to nineteen per cent which are classified as miscellaneous and undetermined. Of course, the mortality is higher in acute cholecystitis, but attention must also be given to the higher percentage of mortality in the latter decades of life.

In consideration of these various causes of postoperative death, one may feel that a certain percentage of them may be avoided. Some deaths from peritonitis, hemorrhage, and shock may be avoided by greater care and better technic in the operation, by making an earlier diagnosis, and urging operation before the patients are in the latter decades of life where they stand operation badly and have less resistance, and perforation or gangrene of the gall-bladder is more frequent. Cardio-renal complications may be diminished if the patient has not a sufficiently acute fulminating process, by adequate preoperative preparation, and it should be kept in mind that a large percentage of cholecystitis cases have cardiac or renal complications, hence the advisability of close cooperation of the physician and surgeon in the evaluation of the time and advisability of operation and preoperative and postoperative treatment. The deaths due to gangrene and perforation would, in a large number of instances, be avoided if the operation were done before the gangrene and perforation had occurred. Pulmonary complications probably always will be with us. They can be lessened if the patient can be protected from exposure immediately before and after the operation, by the avoidance of too tight dressings which compress the lower chest and prevent deep breathing, by moving of the patient in bed after operation and encouraging deep inspiration as soon as the patient is sufficiently conscious and able to respond to suggestion. But a certain number are due to pulmonary emboli or follow massive collapse, due to bronchial occlusion by thick mucus, and

none of the precautions mentioned can effect the former.

In this list of causes of death, "liver-death" is put down as four per cent, and seventeen to nineteen per cent, are classified as miscellaneous and undetermined. Some of these are probably cases in which there is progressive cholangitis, late development of liver abscess, injuries of the ducts, secondary hemorrhage, injury to the hepatic artery or thrombosis of the portal vein, wound separation, and some of the less common complications. There still remains among the undetermined causes, certain fatal cases in which even at autopsy, it is difficult to determine just what has been the determining factor in the unsuccessful outcome. Heyd has called attention to certain postoperative complications following operation on the gall-bladder, in which the causes of death seemed to be in their nature chemical, and not due directly to the surgical procedure. Group I, of which he calls "liver-death," is characterized by hyperpyrexia immediately after operation, coma, and death. This may occur in patients who have not been jaundiced and have not had preoperative temperature, or it may occur in patients who have been deemed to be good operative risks. Group II are cases operated on for obstructive jaundice and in the presence of a diminishing icteric index, develop coma and die. Group III are postoperative cases which develop a picture of extreme shock, thirty-six to forty-eight hours after operation, some of whom improve or may recover after large fluid intake. He considers death in the first two groups due to a disturbed or altered chemistry incident to liver failure. In Group III, there seems to be a more profound chemical disturbance in which renal function and disturbed water balance are pronounced factors. Heyd calls particular attention in these cases to the large fluid circulation in the liver and the necessity where there has been large water loss by increased vomiting, biliary drainage, and excessive sweating, which if not replaced by paraenteral administration of fluids allows the water balance of the liver to become so low as to be incompatible with its normal function and chemistry. Any one doing a large amount of gall-bladder surgery, unfortunately sees some cases

In Table II it is seen that almost one third of the hernia cases occurred in temporary employees. These men in contrast to regular employees did not receive a pre-employment physical examination. Twenty-two were snow laborers taken from the relief roles of the city.

TABLE II

68 Regular Employees—Pre Employment Physical Examination.
32 Temporary Employees—No Employment Physical Examination

Many of these after only a few hours of work would complain of a pain in the groin and after examination, a hernia was found.

A. M., emergency snow laborer, age thirty-five, while shoveling snow January 27, 1935, felt a pain in the groin. He told his squad leader, but did not stop work. Claimant was examined at a hospital three days later where a bilateral hernia was found. This was a recurrent hernia. A bilateral herniotomy was previously performed in December 1933, only thirteen months previous to alleged injury. The State Labor Department ruled in favor of the claimant that the hernia developed as a result of this alleged injury, and the claimant was reoperated and received compensation.

F. F., age fifty-nine, emergency laborer, was pushing a snow shovel January 28, 1935. Claimant had a slight pain. He paid no attention to it and continued working. Three days later pain was worse. *Diagnosis* Large left and small right inguinal hernia. The Labor Department referee ruled there was causal relation, and the claimant was operated upon and received compensation for the resultant disability.

Two of the emergency snow laborers were wearing trusses at the time of injury and admitted having worn trusses for inguinal hernia for several years. Naturally, these cases were disallowed.

When a claimant presents himself at the Medical Department of the Compensation Division of the City of New York with a hernia, a truss is ordered for him without prejudice, that is regardless of whether we believe the hernia is due to the accident described or not. At a subsequent hearing before the referee of the State Workmen's Com-

pensation Division, in controverted cases, an operation is usually ordered as these cases as a rule are decided in the employee's favor.

Not all patients, however, decide on operation. Table III shows the treatment of these cases.

TABLE III

Operation	41
Truss	57
Injection treatment	2

The legal question of causal relation is not important in the cases that refuse operation, as there is no disability while the claimant wears this support. In many cases, the referee will postpone decision on the question of causal relation until such a time as the claimant decides on an operation.

It is interesting to review briefly the cases which were considered not compensable at the Labor Department (Table IV).

TABLE IV—DISALLOWED CASES

Regular employees	4
Temporary employees	5

Regular Employees

1 A. M., age forty-three, employed four years, appeared for physical examination prior to change of title from extra man to regular sweeper in the Sanitation Department. He was rejected when an incipient bilateral direct inguinal hernia was found. He thereupon claimed that he was lifting a can of ashes two days before when he felt a pain in the right groin.

2 G. W., age forty-one, fourteen years in service, Plant and Structures employee, tripped and struck right groin against corner of iron bar. Rested a while and then continued working. Examined by the city physician the following day when a right direct inguinal hernia was found, but no local evidence of trauma.

3 F. H., age sixty-one, employed nine and one-half years, Plant and Structures employee. During the day, lifted a heavy valve. He had no pain and worked the entire day. That night noticed lump in groin. *Diagnosis* Right direct inguinal hernia.

TRAUMATIC HERNIA

JULIUS DAVIS, M D, *New York City*

This report is an analysis of one hundred consecutive cases of hernia seen in the Compensation Division of the Law Department of the City of New York, occurring in the first half of the year 1935

From a medical standpoint, traumatic hernia is a very rare condition. By a traumatic hernia, we mean a hernia that has developed with an actual tearing of the peritoneum as a result of increased intra-abdominal pressure, or as a result of tearing or stretching of the inguinal ring, or other hernial exit following injury. The symptoms arising from such a traumatic hernia would be

- 1 Severe pain and prostration
- 2 Immediate disability, the patient stopping work at once
- 3 Ecchymosis may develop at the site of the herniation
- 4 The accident should be of such serious import that medical aid is sought at once

In contrast to this, we have ordinary hernia which develops as a result of congenital weakness. There is a gradual stretching of the abdominal opening with the formation of a sac. When bowel or omentum enter this sac from strain, such as coughing or from muscular effort, the sac has existed for some time. If the contents enter the sac suddenly, there will be a complaint of pain, but the pain is in no wise severe enough to disable the patient. He continues working. If the sac fills slowly, there will be no complaints of pain, but when the patient sees the mass he will ascribe it to some specific incident in the course of his employment such as lifting a heavy object or cranking a car. From a medical standpoint we know that the hernia has existed and developed over a period of many months or years. Legally under the Workmen's Compensation Law of New York, the specific trauma to which the claimant chooses to ascribe his hernia is frequently ruled as the cause, and the worker is entitled to hospitalization, surgical treatment, and a minimum of eight weeks' compensation.

The referee in reaching this decision is guided by the evidence. The claimant will testify that on a particular day at a specific time, after an ordinary occupational stress, or strain, he felt a pain in his groin. Usually he does not stop working. His physician will send in a medical report in which his answer will be yes to the following questions: (1) Is the claimant's present disability a result of the injury above described? (2) In your opinion was the accident as above described, a competent producing cause of the injury sustained?

The employer or insurance carrier may produce a physician who will testify to the contrary. The referee cannot be criticized for ruling in favor of the claimant when the physicians disagree.

Harvey Stone¹ states

If a decision grants compensation to a workman for hernia, it does not follow that the hernia was caused by the work, but simply that under the provisions of the law, a man developing a hernia in the course of employment is entitled to compensation. As a matter of fact, medical opinion is strongly opposed to the view that ordinary muscular effort is anything but a minor contributory influence in the development of ordinary forms of hernia.

TABLE I—VARIETY OF HERNIA

VENTRAL Incisional 1, Epigastric 2	
INGUINAL (a) Unilateral, 66 (b) Bilateral 19, (c)	
Post operative recurrence, 12	
(8 Unilateral, 4 Bilateral, and 1 Second Recurrence)	
(2 incarcerated and 7 previous operation on other side.)	

Table I is an analysis of the variety of hernia seen. It will be noted that thirty-eight of the 100 cases had evidence of pre-existing weakness—i.e., either recurrence, evidence of hernia on the opposite side without complaints or scar of operation on the other side in the inguinal region. The nineteen cases of bilateral hernia usually complained of pain on one side only. When informed that they had bilateral hernia, they assumed that the alleged trauma was the cause for the condition on both sides.

PARTIAL (BILATERAL) ADRENALECTOMY

For Malignant Hypertension

LOUIS FRIEDMAN, M D and A. A. EISENBERG, M D, *New York City*
From the Surgical Service, Department of Pathology, Sydenham Hospital

The etiology of essential and malignant hypertension is still in a controversial state. None of the theories so far advanced have an unassailable foundation.

Medical aid has been only symptomatic relief, if that, while the progress to fatal ending has been uncontrollable and inevitable. Because medical treatment has been a failure, various surgical procedures have been advocated and tried backed by quasi-theoretical reasons, none of which so far will bear severe criticism. The line of attack for this empirical surgery has been the adrenals and the sympathetic system.

I do not wish to offer conclusions, only state clear facts. Seven cases were studied and operated upon in order to determine, if possible, the value of partial adrenalectomy in essential and malignant hypertension, only two were ideal essential hypertensives. There were five bilateral and two unilateral, altogether twelve partial adrenalectomies. The convalescence has been generally smooth and uneventful, with an immediate mortality of two—Case 6, acute adrenal insufficiency, Case 7, cerebral hemorrhage. Unfortunately, these two were the ideal essential hypertensives, wherein observation would have been of the greatest value.

All of them have been advanced cases, length of illness from three to eight years. All of them were hopeless, with no relief from medical care.

Five of the cases were advanced with secondary cardiorenal changes, while two were early essential hypertensive. The ultimate results are anything but satisfactory with only comparatively temporary improvement in symptoms, and lasting improvement altogether disappointing.

While all who survived the operation had a considerable drop in tension, in only two did the tension remain much lower for more than two years, than be-

fore operation, and all have had symptomatic relief for only a short period.

Two patients died from adrenal insufficiency, one acutely, one several months after operation, one died from cerebral hemorrhage four months after one side was operated upon with only temporary drop in pressure and moderate symptomatic relief. One died from cerebral hemorrhage twenty-four hours after a one side partial adrenalectomy.

Out of seven cases only one is alive since this study was started, and in good health as compared to before operation—Case 4, with tension remaining much lower than before.

All seven cases here reported had about the same symptom complex. Headache, dizziness, nausea, loss of weight, and myocardial damage was present in four cases, renal damage in three, blood pressure from 200 to 290, systolic, diastolic proportionately high—eyeground damage—vessel spasticity in five cases. * Age ranged from nineteen to forty-three.

Nevertheless, partial adrenalectomy should be given a fair trial, since other medical or surgical measures are by no means encouraging in very carefully selected cases of malignant hypertension, wherein the presence of albumin is low, the eyeground changes and myocardial damage not too far advanced, and Van Slyke clearance fairly good. The ideal cases, however, would be the essential hypertensives without any organic changes, but here the difficulty will arise to convince the medical man of its probable value since it is an empirical procedure, and to convince a symptomless hypertensive patient.

I feel that like patients having tuberculosis, who receive sanitarium treatment and all the benefits therewith, so hypertensive cases should be given the benefit of institutional care, with sunshine, fresh

* Complete clinical history available on request.

4 R B, age forty-three, hospital employee, "strained myself" lifting a patient. He did not notice lump till one week later. Had no pain and lost no time from work.

Emergency Employees

1 and 2 Emergency snow laborers who had been wearing a truss one year or more prior to the alleged accident.

3 S J, age thirty-eight, temporary snow laborer, gave two different histories. (a) Using pick to chop snow, he strained his right side. (b) Struck his right groin with a pick handle. Worked the entire day after the injury. Reported the accident ten o'clock that evening. He was examined the following day at the Sanitation Clinic. A right inguinal hernia was found.

4 J J, age fifty-two, emergency snow laborer, was shoveling snow and "ruptured himself." Continued working. He sought no medical aid until ten days later when a left direct inguinal hernia was found. He felt no pain at the time of the alleged injury.

5 J H, age twenty-six, hospital employee, employed one month as a stretcher bearer. Felt pain in the right groin. Examined by a hospital physician the following day. Lost no time from work. *Diagnosis*: Dilated right external inguinal ring (no actual hernia).

From the cases disallowed, we can draw the following conclusions:

1 Cases developing in the course of employment without pain will often be disallowed.

2 Cases where there is no actual hernia, but only a large external inguinal ring or a large canal may be disallowed.

3 The referee may doubt the credulity of a claimant.

Ninety-one cases remain. Of these, the large majority were ruled as compensable because they occurred during the course of ordinary occupation stress of the worker and he complained of pain. In some of the cases in which the claimant did not desire an operation, decision was deferred.

A large proportion of the compensation claims for hernia can be eliminated by careful pre-employment examination and subsequent periodic examination.² The Surgeon-General's Office at Washington reported 238 per cent of drafted

men during the World War suffered from hernia.

Wylls Andrews³ states that about six per cent of all males in the community are incapacitated by hernia for appointment in the army, navy, police or fire departments. From my own experience, I can agree with him. In the course of pre-employment examinations in a large wire factory, I have found about five per cent of the applicants have hernia or potential hernia (large inguinal rings with impulse on coughing). Of more than one thousand men who were found free from hernia, and who have worked for the past four years at heavy manual labor, only two developed a hernia in the course of their employment. This is in direct contrast to the very large number of claims prior to the introduction of pre-employment examination at the factory plant.

The question of hernia as an industrial disease has never been decided at the State Labor Department. Can dilation of the inguinal rings and canals occur slowly as the result of constant exertion with the gradual production of hernia? It would be more reasonable to believe this than to assume that one lift actually produced it.

Summary

1 Compensation claims for hernia can be reduced to a minimum by careful pre-employment examination. Any cases overlooked can be discovered on subsequent periodic examination once every year or two.

2 Hernia developed in the course of employment accompanied by pain which frequently is not disabling, is usually ruled compensable in New York State.

3 It is suggested that definite standards be set by the Medical Profession and recommended to the State Labor Department as to what cases be ruled compensable.

Fig 1 Adrenal gland Much fibrosis of the capsule. Blood vessels show thickened walls, in one, the lumen is obliterated. (Case 5, first operation)

air, diet regulation, etc, for at least a year after operation

Postoperative Follow-up

CASE 1 J B Blood pressure before operation averaged 230/160—250/160

Postoperative in hospital 190/120—160/150—170/160 May 21, 1935—170/120, May 29—210/150, June 12—190/150 At this point patient was generally improved, there were no headaches or nausea, but often precordial pain, and he admitted a general feeling of well-being. However, family disturbance, worry, excitement, nervous upset caused severe setback and he went to a sanitarium in Philadelphia. Blood pressure then was 190/120,

five c.c. albumin in urine, precordial pain. Several months later developed symptoms of adrenal insufficiency. Progressive asthenia, cortin was of value for a time, but patient died in January 1936

CASE 2 S G Blood pressure before operation averaged 264/156—280/160

After operation in hospital blood pressure dropped to 160/110—180/136—200/120 July 24, 1935—Feels well, no headaches or dizziness. Blood pressure—220/170 October 24—Feels better, no headaches or nausea, gained weight, was readmitted for second operation, while in hospital pressure was 240/130. Patient developed a hemiplegia. Second side was not operated upon for the above reason. Four months later, blood pressure was again higher with return of headaches, etc.

CASE 3 S B Average blood pressure before operation 240/170 After operation in hospital 220/140—160/130

April 1935—Blood pressure—210/160 June 12—Has had three attacks of severe headache—blood pressure—190/150—albumin, 3 plus, July 25—Feels well, no headaches, gained weight. October 8—Has been working, no headaches, sleeps well, blood pressure—190/150

April 8, 1936—Blood pressure—180/130 April 16—Blood pressure—190/130 At this

Fig 2 Kidney A thickened vessel near two glomeruli, dilated and hyperplastic glomeruli. Moderate glomerular changes (Case 6, first operation.)

time, patient felt that the operation had been well worth-while as he was in better health than before the operation. Adrenalectomy was of no ultimate value, however, as the patient has since expired.

CASE 4 D. K. Before operation blood pressure averaged 260/140—240/122

After operation, the patient experienced general improvement, fewer headaches, weight gain, no nausea or vomiting, and felt that the operation was worth-while. Postoperative blood pressure average—210/130—150/120. Many months of follow-up showed general improvement, gained weight, no headaches or nausea. Blood pressure ranging well below original preoperative pressure. 190/130—170/120—200/140. I feel that this patient has been definitely helped by operation.

July 1936—Blood pressure—180/140 and doing well.

February 1937—Feels great deal better. Blood pressure varies 160 to 190.

CASE 5 C. D. Before operation blood pressure averaged 295/145—260/130—220/140. After operation in hospital 'pressure' averaged 190/110—140/130.

Follow-up progress Always a rise of twenty to thirty points before menstruation. Blood pressure 180/130—200/120. This patient unquestionably has been benefited by operation. (Fig 1) The oldest postoperative observation. General improvement, no headaches. She has, however, often precordial attacks. Patient feels the operation was well worth-while.

July 1936, blood pressure 180/130. Pre-menstrual rise controlled by x-ray. Myocardial failure caused death in November 1936.

CASE 6 E. R. Blood pressure before operation averaged 230/120—250/130.

After operation in hospital, blood pressure averaged 200/120—170/120.

Was much improved after first partial adrenalectomy, (Figs 2-3) no headaches or nausea, gained weight, pressure again rose to 240/130. Second operation six months later (Fig 4). Died from acute adrenal insufficiency.

CASE 7 H. D., age nineteen. Blood pressure before operation averaged 190/120—240/160. Van Slyke clearance, good. During operation blood pressure did not drop as usual in all other cases. After operation blood pressure rose to 280/225, and the next day weakness developed in left upper and lower extremities followed by coma. Complete left hemiplegia and extus. Histological section of adrenal showed markedly thickened capsule, vessels tremendously thickened, lumen reduced to a mere narrow slit, media markedly hypertrophied, and the cortex moderately hypertrophied.

Fig 3 Muscle. Very striking blood vessel is seen at arrow, ratio of wall to lumen is about two to one, instead of one to two. Subintima nucleated. (Case 6, first operation)

The several lines of surgical endeavor for the control and possible cure of hypertension, so far are

- 1 Crile's adrenal denervation¹
- 2 Ganglionectomy, Sympathectomy with partial Adrenalectomy²
- 3 Rhizotomy, anterior and posterior dorsal and lumbar root section
- 4 Bilateral, partial adrenalectomy

The multiplicity of methods weakens the probable correctness or infallibility of each. Nevertheless, one or a combination of some of the above procedures may

be an important factor in the cure or alleviation of malignant hypertension. As White ("The Autonomic Nervous System" 1935), correctly states, "The whole matter of surgical intervention in severe hypertension is still so much in its infancy, that it is impossible to form any final judgment."

It seems, however, that some of the proposed operations through remote attack, by way of the sympathetic system

problem of the etiology of hypertension. Individual reaction of this class of patients to excitement, physical and mental strain, environment, interrelated internal secretion, the chromaffin system, the possible effect of sympathin—all have a direct bearing on etiological background.

Dr Crile has performed unilateral adrenalectomies in hypertension with disappointing results, but his cases reported were not pure malignant hypertension.

Fig 4 Adrenal gland Very markedly thickened vessels with much reduction of lumina (Case 6, second operation)

point directly and ultimately at the suprarenal glands, thus attempting vasomotor control. Josue in 1903 and later Vaquez were the first to associate the adrenals as a possible causative factor in malignant hypertension. Progressively abnormal low blood pressure in Addison's disease, the drop in pressure to normal following removal of adrenal tumors, stimulated the idea that if surgically the adrenal secretion and output is decreased, *ipso facto*, the blood pressure will be lowered and so stabilized. It may sound plausible, but practically applied it has by no means been proven so as yet.

There are other important and still unknown factors which enter into the

Later bilateral adrenal denervation was advocated by him, but detailed and ultimate results so far have not been published. Dr Crile's general conclusion being that denervation in hypertension has given disappointing results. Nor has this method gained support of other surgeons in the treatment of malignant hypertension.

A revised and direct attack was suggested in 1934 by DeCourcy⁸ which consists of a partial bilateral adrenalectomy, including both the cortex and medulla, a two-stage operation with an interval of three to four months, based on the hypothesis that essential and malignant hypertension is due to excessive secre-

tion of epinephrin by hyperplastic suprarenals. Hypertension being still the mysterious disease that it is with many debatable opinions as to its etiological background, the dogmatic statement cannot as yet be made that "hypersuprarenalism" is the primary and only cause of hypertension.

That the adrenals, however, play an important role in blood pressure control cannot be doubted as instanced in the progressive lowering of tension in Addison's disease and the acute and alarmingly keen drop in pressure in acute adrenal insufficiency sometimes following surgical trauma to the adrenals, contra, the phenomena of excessive rise of blood pressure during manipulation of the adrenal while performing adrenal denervation for recurrent hyperthyroidism.

While the analogy which DeCourcy^{4,5} draws between the overactive thyroid and overactive adrenal is questionable and yet to be proven, the *empirical* trial of partial adrenalectomy is worth-while in carefully selected cases of hypertension, being a direct attack on the gland secreting adrenalin, which has at least, if not altogether, some definite effect on vasomotor control. *It is, however, by no means devoid of danger*, for possible and unavoidable surgical trauma to the adrenals can cause profound and grave constitutional reactions from resulting hypofunction, and death from acute adrenal insufficiency.

Crile reports two deaths from operative trauma to the suprarenals following adrenal denervation, technically a much simpler operation than partial adrenalectomy. Both developed adrenal insufficiency. Autopsy showed, in one case, bilateral degeneration of the adrenal glands, in the second case, adrenal apoplexy, extensive hemorrhage within the medulla with necrosis of adrenal tissue. Rogoff⁶ reports a case of Addison's disease and death following adrenal denervation. I report death of Case 6 from acute adrenal insufficiency and progressive adrenal insufficiency in Case 1 several months after partial adrenalectomy.

The operation through an Alberran incision is not particularly difficult, usually technically easier on the left side, but should be performed *with great care and gentleness* not to disturb the blood sup-

ply of the gland, and accomplishes, if the assumption is correct, not only less adrenal output, but it denervates the gland as well.

It is timely to call attention to the anatomical fact that *in vivo*, the adrenal is never reposing directly on the upper pole of the kidney as pictured in all textbooks (Fig 5). This is probably the reason that the adrenal is never seen

Fig 5 Fairly constant anatomical location of adrenal, one to three inches of intervening perirenal fat between upper pole of kidney and lower margin of adrenal, blood supply and distribution of fine sympathetic nerve filaments derived from ganglion.

and rarely if ever injured during nephrectomy. The kidney is a comparatively freely movable organ. The adrenal is a very much fixed organ, well surrounded by fat, plastered down to the lumbar muscles by connective tissue and fine nerve filaments coming from the sympathetic ganglion supplying it, is one to three inches away from the upper pole, and often found implanted high up under the diaphragm. This distance is increased when the kidney is retracted

downward in order to gain approach to the gland. Due to its color and shape it is easily recognized after the periadrenal fat is separated.

One learns to palpate it and recognize it by its shape and flat rather rough triangular cortex. The part of the adrenal gland to be removed must be very carefully but thoroughly mobilized. In doing this the fine nerve filaments entering the under surface are severed either with fingers or sectioned with scissors. I have found the eight inch Allis clamp a very convenient instrument to grasp the gland with. I place a curved artery clamp on the outer half, removing that much or more, leaving the inner half which is attached to its blood supply. Often the gland is very friable and tears easily, necessitating the removal in sections. It seems that the crushing effect of the clamp is sufficient to control bleeding, but it is safer to use a running catgut suture. Rubber dam drain for three or four days to drain off exudate resulting from operative trauma is necessary.

The amount of adrenal to be removed to be of therapeutic value and *with safety* is still an unknown quantity. DeCourcy removed two-thirds to three-quarters in two stages and lately advocates a lapse of two to three months between the two stages based on the theory that in that time the second gland to be operated upon undergoes hyperplasia and hypertrophy. My observation in partial adrenalectomy so far has not convinced me of any macroscopical evidence of compensatory hypertrophy of the second gland.

While it is well-known that excision of one of "twin organs" produces hyperplasia and hypertrophy of the remaining organ (kidney, one lobe of the thyroid, testicle?), no proof is recorded of hyperplasia or hypertrophy having taken place in the adrenal after removal of part or whole of one gland. Though the two cases studied (5 and 6) are hardly sufficient to draw conclusions, the pathologist's report on part of the two adrenals removed four and six months after the part of the first was removed, showed that there was some hyperplasia and hypertrophy, which of course, may have existed at the time of the first operation.

Crile advocates in adrenal denervation, a safety period of about a week to ten days between two stages, so as to give the first denervated gland an "opportunity to make a physiological recovery," and where there is considerable systematic reaction, a longer interval period.

It is somewhat premature to accept the theory that the secondary rise in blood pressure after an initial drop following one-sided partial adrenalectomy is due to quick regeneration of the remaining adrenal or compensatory hypertrophy of the unoperated adrenal. Nevertheless, because of possible operative trauma to the remaining adrenal of the first side operated, the three to four month interval is an excellent suggestion, safe to follow.

The margin of safety after removing one-half or three-quarters of the gland leaving one-quarter or one-half of remaining gland to carry on function for normal living may be a good margin of safety for many, but may not be for the next patient. Lack of knowledge of the exact functional state of the remaining gland on the operated side adds materially to this uncertainty. If this remaining gland through operative trauma has been damaged, and atrophies, removal of too much gland on the second side may prove disastrous. (Case 6)

The often unavoidable surgical trauma to the remaining portion of the adrenal which is left after partial adrenalectomy, can cause temporary suppression of function. So far no recorded observation has been made of the possible amount of damage done or of its physiologic and functional recovery. Adrenal tissue, the cortex particularly, is supposed to rapidly regenerate, but this happens during normal physiologic function in an untraumatized gland. What happens in a surgically traumatized one?

Rogoff has described a "significant symptom," costolumbar pressure reaction, and interprets it as an evidence of progressive adrenal degeneration. He observed this symptom and suggests its presence in Addison's disease. To quote Rogoff:

The presence of this sign in Addison's disease may be interpreted as evidence of active inflammatory or degenerative processes in the gland. Cessation of these processes is followed by disappearance of

the symptom, and its reappearance indicates renewal of the process. If after having been observed repeatedly, the sign finally disappears as it does often in the late stages of the disease, it has been found generally that the gland has practically entirely degenerated or fibrosis has terminated the process.

If partial adrenalectomy will meet with success in the treatment of essential or malignant hypertension, the Rogoff sign and its interpretation should be of great value to determine the state of the remaining adrenal, after the part of one adrenal has been removed. Granting that Rogoff's observation of this sign is correct in Addison's disease, costolumbar pressure reaction should be of great guiding value to determine the safety of the second partial adrenalectomy.

The amount of gland on each side removed in five of my cases was more than one-half, and proved to be therapeutically and functionally the proper amount and within the limit of safety, but in the sixth following the first operation, not particularly difficult, symptoms of adrenal upset followed: low blood pressure, rapid pulse, high fever, cyanosis, mental apathy. Six months later, when the second side was operated, very profound constitutional symptoms followed with all the classical symptom complex of acute adrenal insufficiency, and death in forty-eight hours. Examination of remainder of second adrenal gland showed diffuse hemorrhage.

The pertinent question arises: How much surgical damage occurred to the remaining right adrenal at the first operation? Did it regain its physiologic function?

The second operation performed six months later was very simple, easy exposure, the gland was dissected very gently, only one-half was removed, and still death from acute adrenal insufficiency followed.

Symptoms of Acute Adrenal Insufficiency

Five to six hours following operation: rapid and soft pulse, low blood pressure (a drop of 100 to 150 points), widely dilated pupils, high fever (up to 106° F), cyanosis, general mental and physical

apathy, which gradually changes to semi-consciousness and coma, paralytic ileus, and dilated stomach with large amount of fluid content—later, blood pressure so low that a manometer reading is unobtainable, spasticity of muscles, all reflexes slowed, respiration may be elevated, and dark brown pigmentation of skin. *Treatment should be immediate.* Ice packs for fever—intravenous salt and glucose, 750 to 1000 cc or continuous, properly gauged by chloride and sugar content of blood. Replacement therapy by Eschatin (adrenal cortex) or the cortical hormone of Swingle and Pfiffner, carbon dioxide oxygen for cyanosis, ephedrin $\frac{3}{4}$ gr every three or four hours, high colonic irrigations and Levine tube drainage when indicated. Use of caffeine, sodium benzoate, and digofoline is questionable except when myocardial involvement and signs of congestive heart failure are present.

Blood pressure. The interesting observation has been noted that during the operation for recurrent hyperthyroidism, adrenal denervation causes a considerable rise in blood pressure simply by the handling and moderate trauma to the gland, in hypertension, with a greater amount of trauma to the gland, the tension drops many points, sometimes alarmingly so. This was observed in cases operated under avertin anesthesia.

Six cases experienced a drop of from forty to one hundred twenty mm systolic following the first operation, the diastolic usually less, then the pressure again rose to a higher level before the second side was operated, then again a comparatively good drop after the second side was operated, again a rise, then the maintenance of a fifty to one hundred twenty mm drop from the original level, but not permanent. In only two cases was there a sustained drop for about two years.

Van Slyke clearance. In all instances the clearance became much higher twenty-four hours after the first side was operated upon showing the effect of lessened contraction and spasm on the kidney arterial system. After a few days, there would be a drop in clearance, again a decided rise after the second partial adrenalectomy, then again a drop, then a leveling to much higher clearance than before operation.

Conclusions

From the pathological viewpoint the following conclusions seem justifiable

1 The cases dealt with in this paper are those of malignant nephrosclerosis (or malignant hypertension), i.e. a primary diffuse vascular disease "of which malignant nephrosclerosis represents the renal end-stage"

2 Clinically they were young persons (their ages ranging between 20 and 43), with marked hypertension (the average being about 250/150, a low Van Slyke clearance (20-30 per cent), and retinal angioathy

3 Without any attempt whatever at

drawing any conclusions, the following is set down just as an observation

(a) The lesions in the adrenals consist of marked thickening of the capsule and of the trabeculae, at times being very pronounced.

(b) The vessels, both in the capsule and in the periadrenal fatty tissue, as well as in the muscles and the kidneys show not the ordinary atherosclerotic changes but the thickening of the media, which, apparently, is not inflammatory but due to muscular hypertrophy. These apparently are the changes which are referred to as "productive endarteritis" ("accelerated form of arteriosclerosis" of Klemperer and Otani)

(c) No lesions referred to as "necrotizing arteriolitis" were noted

WHEN REAL DOCTORS ARE WANTED

"The Unsung Hero of the Great Flood" is the title of a three-page article in the April 1 issue of the *New York State Journal of Medicine*. This article is written from a description of Indiana flood conditions in our March JOURNAL, and it goes on to state that while the story is about Indiana, it applies equally well to flood conditions and medical relief in the states of Ohio, Kentucky and Illinois. The writer enthusiastically discussed the role of medicine in this, the greatest flood in the history of the Ohio Valley. We are grateful for the comment and wish that every member of our Association might read it. The

citizenry of this country occasionally wanders away from the beaten path and listens to the blandishments and "come on" arguments of the quack, the irregular, the patent medicine radio blah and the pseudo-healers, but we note that in times of stress and upon occasions when local and national disasters of various sorts threaten, the call is "Get the doctor," and they mean a physician, a Simon-pure M.D., a Man of Medicine! Never in the history of the profession has this call been made in vain in times of great need.

—*Journal of the Indiana State Medical Association*

HOW DO THEY DO IT?

Medals or ribbons or something seem due Rochester and Schenectady, which appear in the automobile death tables with actual reductions while other cities show a tragic increase. In the sixteen weeks ending April 10, Rochester had ten deaths due to motor accidents in the city, as against fifteen last year, and Schenectady had two

as against three last year. In contrast, Buffalo's fatalities rose from thirty-nine to fifty-four, New York City's from 226 to 302, Syracuse's from two to ten, and Yonker's from one to four. Albany kept level at four and four, and Utica at two and two. The figures are from the Census Bureau.

METHEMOGLOBINEMIA AND PRONTYLIN

J FRANKLIN STONESS, M D, *New York City*
Associate Otolaryngologist, Post-Graduate Medical School
and Hospital, Columbia University

Does the use of prontylin tablets produce in the patient a methemoglobinemia?

* * *

G.H.P., a physician, was admitted to Post-Graduate Hospital on January 12, 1937, about 3 30 A.M. suffering from acute pain in left antrum region. Previous to admission patient had been taking care of himself at home, as he had been ill with influenza for nearly two weeks. Temperature on admittance was 100.4, pulse rate eighty, respirations twenty.

Treatment at home consisted of the following: January 2-6, patient stayed up and took three aspirins grv per day, three acetyl compound consisting of acetyl salicylic acid gr 3½, phenacetin gr 2½, caffeine gr ½—three per day, also took pill containing benzoic acid, one-two per day, and pill containing atropine—two per day—the amount in each case not known as it was an old prescription used previously. January 6-11 was in bed at home. Took aspirin grv, and acetyl compound tablets as described above three-four times daily. He took amytal grs 1½ at night. He used ephedrine inhalant as a spray, and took two-three of the benzoic and aspirin pills as described above daily.

The nose and throat intern was advised by me to give a four per cent cocaine and adrenalin pack in the left side of nose in order to establish better drainage from the left antrum. Ephedrine one per cent in normal saline was also given as a spray. Temperature at 7 A.M. was 101.4, pulse ninety-two, respirations twenty.

I saw patient first at 9 A.M. and found the left antrum extremely tender. Patient complained of severe pain in that area, in and about the teeth on that side, and in fact, the whole left side of his face. On examination of the nose, found inferior turbinate on the left side pressing over to the septum and filling the space, with pus oozing out of the middle meatus. The whole nose was so tender that I was unable to pack the left side, so I ordered gr 1/6 of morphine sulphate given, and began with the use of small tampons pressed out of a solution of ten per cent cocaine and adrenalin—half and half. After desensitizing the area, I did an antrum puncture on the left side, preferring this to irrigat-

ing through the natural opening, and washed out a fair amount of pus.

This was sent to the bacteriological laboratory for culture, the report coming back the following day, January 13, showing *Streptococcus hemolyticus*, of many colonies in one loopful of material.

At the time of admittance on January 12, I ordered aspirin gr x bicarbonate of soda gr x q 4 h, with forcing of fluids, and an ice cap to left antrum area to relieve pain, as needed for comfort. After the irrigation nose bled somewhat, and at 2 30 P.M. an adrenalin pack was lightly inserted. Later, at 5 P.M. a ten per cent cocaine pack was inserted in the left nostril and left there for ten-fifteen minutes.

I saw patient again at 6 P.M. and gave nasal irrigation. At that time, the returns showed a considerable amount of pus. The ephedrine spray one per cent in normal saline was used and this spray was used q4h throughout the illness. At 7 P.M. temperature 104.4, pulse 84, respirations twenty. At 10 P.M. nasal irrigation was given again. Temperature at that time 101.8, pulse 100, resp twenty-four.

January 13 At 4 A.M. temperature 101.4, pulse ninety, respirations twenty-four. Patient complained of great pain in left side of face, but refused medication at this time. At 8 30 A.M. nasal irrigation was given. These nasal irrigations were all given from right side forcing return through left side, thereby not carrying any infectious material backwards. At this time temperature was 102, pulse ninety-six, respirations twenty-two. At 12 P.M. codeine gr ¼ was given. At 4 P.M. cocaine and adrenalin pack was given, but area was so tender that gr 1/6 morphine sulphate had to be given in order to allow packing. A nasal irrigation was then given, and returns showed a considerable amount of pus. I then gave an argyrol pack, while mucous membranes were desensitized on that side, and left this in for thirty minutes. At 6 P.M., the patient complained of severe burning in the left side of the nose. Intern advised codeine gr ½ with luminal gr 1, at the same time a few gtt. of twenty per cent argyrol was instilled in left conjunctival sac, as patient complained of left eye irritation.

Prontylin was first used at 6 30 P.M., because the culture from the antrum irrigation had only been reported at 12 P.M. I discussed the use of prontylin with a professor of the nose and throat department who claimed good results in several cases, by using four tablets three times daily. This dosage was given.

At 7 P.M. nurse reported left eye swollen somewhat and reddened, with small amount of purulent drainage present.

January 14 At 12 A.M. luminal gr $1\frac{1}{2}$, triple bromides gr thirty was given for pain and sleeplessness, and prontylin tablets were again given. At 2 30 A.M., same night, temperature was 104.4, pulse 128, respirations twenty-six, patient became cyanotic, unable to breathe easily, rather frightened, and restless. Caffeine sodium benzoate half ampoule was ordered by his medical doctor, Dr. Currence, who had also been taking care of him, as I had been called to treat the sinus condition only.

At 9 A.M. a blood culture was ordered by a medical internist, and a bacteriologist began desensitizing the patient against serum. As soon as this was done, anti-streptococcus serum was given intravenously, although as yet there was no report of blood culture. Intravenous Streptococcus injections were continued for several days by the bacteriologist.

At 10 A.M. nasal irrigation was given, ephedrine spray was used, and argyrol grtt. twenty per cent. At this time all aspirin was ordered discontinued by me. At 12 40 P.M. codeine gr $\frac{1}{4}$ and luminal gr $\frac{1}{4}$ were given. Temperature 3 40 P.M. 101, pulse ninety-two, respirations twenty. Another medical consultant was called in at 4 P.M., and after careful chest examination nothing to indicate pneumonia was found. It was decided to discontinue any sedatives except codeine gr 1 with triple bromides gr 30, this to be given only when needed. Prontylin tablets were continued, nasal irrigation, ephedrine spray, argyrol grtt. twenty per cent, and ice pack to left antrum area also were continued. Patient remained cyanotic, particularly about the lips and seemed very exhausted. Sputum examination was ordered. Report showed sputum negative for pneumonia Types I, II, III, V, VII, and VIII. At 11 P.M. temperature 101.8, pulse 100, respirations twenty-six.

January 15 A roentgenogram plate of chest was taken, but nothing indicative of pneumonia was found.

January 16 The blood culture was negative after forty-eight hours, and was not positive at any time up to the time patient left the hospital. An oxalated blood specimen was sent to the laboratory for spectroscopic examination for sulphhemoglobinemia and methemoglobinemia, and returns showed methemoglobinemia. All prontylin was stopped by me at this time, although there was no literature known to us which stated this drug as a causative agent of methemoglobinemia. Also, all coal tar products were stopped.

Nasal irrigations were continued, patient placed on high caloric diet, and kept in oxygen tent, this latter for the purpose of trying to clear up cyanotic condition. Patient was kept in tent for two-three days. Temperature ran about 100, pulse about 100, respirations about twenty-two to twenty-four during this time.

The blood counts are as follows

		Erythrocytes	Leukocytes	Hemo globin %	Color Index
Jan 12	4,600,000	5,600	90	90	
14	4 350,000	13,800	85		
15	4 370,000	9,100	90	1 02	
19	4,220,000	7,450	77	90	

DIFFERENTIAL (count of 100)							
		Polys	Eosin	Bas	Monocytes	Sm. L	Large L.
Jan 12	87	0	0	2	2	2	
14	70	0	0	4	19	7	
15	85	0	0	4	12	5	
19	81½	0	0	1	14,	3½	

January 25 Another spectroscopic examination of blood was negative for methemoglobin. Urine throughout the illness was essentially negative.

Blood pressure on January 21 was 102/62. Temperature was normal from January 20 to 26, and patient was discharged on the latter date.

The questions are, has this patient an idiosyncrasy towards drugs, did the use of prontylin tablets together with the use of coal tar products before and after entering the hospital cause methemoglobinemia, does the use of prontylin tablets alone cause methemoglobinemia?

THE DOCTOR'S WIFE IS CELEBRATED IN SONG

A delightful feature of the annual meeting of the Woman's Auxiliary to the Medical Society of New Jersey was a

poem by President Herrman of the State Society, which he read at the luncheon of the Auxiliary.

PSYCHIATRIC TREATMENT IN AN INSTITUTION

Case of a Psychoneurotic Boy

SAMUEL Z ORGEL, M.D., *New York City*

Adjunct Psychiatrist, Mt Sinai Hospital, Psychiatrist Hebrew Sheltering Guardian Society, Pleasantville, N Y, and Hebrew Orphan Asylum, New York City

Charles S was nine years four months old when admitted to the Hebrew Sheltering Guardian Society at Pleasantville, in April 1929. Previous to his admission he had received psychiatric treatment at several hospitals. In 1927 at the first hospital, he was thought to be emotionally unstable and they advised removal from the home. In 1928 after a conference between the parent and the school, he was placed under observation in the Bellevue Psychiatric Hospital. He was under observation from March 31 to April 14, 1928, and diagnosed as emotionally unstable (postencephalitis?). A later neurological examination definitely ruled out the encephalitis.

The background of this boy is as follows

The father was born in Roumania in 1886 and came to U S when he was seventeen. He had always been in excellent health. At ten years he was obliged to work and help support the family. On his arrival in the U S with his mother and two sisters, he continued his education by attending preparatory school. His unhappy domestic life has prevented him from keeping up with his interests. Since the birth of Charles he has been playing cards and staying out late at night. His interest in his wife markedly diminished and his hate for Charles was expressed by repeatedly beating him. His lack of interest also extended to the other three children in the home. He admits that his wife does not know how to raise the children and has spoiled them by overindulgence.

The mother was born in Poland in 1894, and was one of seven children. She came to this country in 1911 and went to live with a sister who had previously migrated to the U S. She never had an opportunity to attend school, and supported herself by working in a sweater factory, earning about \$10.00 a week. She married to escape a life of drudgery and have a home of her own. She has always had a nervous stomach and

suffered from constipation. In 1924 and 1926 she had "nervous breakdowns" which she overcame by a short rest at home. She has never taken the medicines the doctors have prescribed for her nor followed their instructions. She has no interest outside of the home. She is attending the O.P.D. of a hospital where she has been diagnosed as a psychoneurotic. She is very much attached to Charles and caters to his every wish. Her overprotection of Charles and continual cursing has caused her husband to remain out of the home until late at night.

Marital relations of parents Mr and Mrs S kept company for three years before their marriage in 1916. During this time and before the birth of their first child they were exceedingly happy together. They regularly attended lectures, concerts, and the theater. With the coming of the children they could not go out together since the mother's freedom was almost entirely cut off. Mr S, although more intelligent than his wife, maintains the old-fashioned opinion that the full responsibility of the home and the children rests upon the wife. He feels that she is too devoted to the children and as a result he often stays away from home part or all of the night. He complains that his wife is a poor housekeeper and cook.

Siblings

Bella Born November 24, 1917, development normal. She has food fads and sleeping habits similar to Charles. Mother considers her easy to manage.

Charles His early developmental history was negative and he presumably got along well. He was thought to be a precocious child since he was able to sing songs when one year old. In his fifth year he suffered from several childhood diseases and his tonsils and adenoids were removed. He began kindergarten at five and school at six. His promotions were regular and he was thought to be a good student. He played truant frequently and would not attend school unless mother took him directly into the classroom.

Read before The Society for Clinical Psychiatry, New York Hospital, Westchester Division, October 15, 1936

The parents have found the boy difficult since infancy. He was always nervous, restless, and a nail-biter. His restlessness became more marked at bedtime so that it took him hours to fall asleep. He would refuse to go to sleep alone and cause a disturbance if made to do so. He slept with his mother until the eighth year and was then forced to sleep with father. Charles at nine years could not dress himself and was helped by his mother. He liked being treated like a baby and enjoyed sitting on his mother's lap and to be coddled like an infant. When he was thwarted he gave vent to violent temper tantrums which took the form of screaming, crying, kicking, throwing objects about the room, and smashing furniture. He would threaten to commit suicide by falling or throwing himself from the roof, and would make false attempts at carrying out his threat. He threw stones from the roof upon people passing in the street, breaking neighbors' doors and smashing windows.

The mother was very much afraid of him and acquiesced to his every wish. He would kick, hit, and pinch her. When he returned from school he would order his lunch and mother would immediately run out and buy it. Despite his attitude towards his mother, she enjoyed having Charles do the things he did. She was proud of the fact that he was known to the entire neighborhood and would recite the boy's latest escapades. Charles associated with boys older and bigger than himself and often fought with them as well as with younger boys. He was a poor loser and on such occasions would run home crying. The school could not understand his truancy since he got on well. In the classroom he was restless and talked excessively. This could be controlled by keeping him busy. He could not take criticism and became discouraged when he was told his work was not up to the mark.

Martha Born October 27, 1925, a spoiled child, drank from the bottle at the age of three years. She has the same food fads and sleeping difficulties as the other children.

Abraham Born 1929. Mother was pregnant with this child at the time Charles was being considered for institutional placement. It was shortly after this child's birth that Charles' behavior became more acute and he was finally placed in the Institution.

Paternal grandparents The father's parents were separated because they were unhappy together. His father remained in Roumania while his mother and the three

children came to the U S. His father was a happy-go-lucky individual who loved his freedom and did not want to assume any responsibility.

Maternal grandparents Both grandparents are dead. The mother's father died of asthma and complications when Mrs S was two years old. Her mother died of starvation during the war at the age of seventy.

Let us review the several factors considered as playing important roles in the development of Charles' problems. The mother found her husband adequate until the birth of her first male child, the patient. At this time she began to neglect her husband. The husband showed his reaction to his wife's neglect by complaining, neglecting her, and staying out late at night. In spite of the loss of her husband's love, we find that she was entirely given over to her child. He slept with her and displaced the father entirely as the mother's love object, thus completely infantilizing the child. This boy's real antisocial and destructive behavior began at the age of five when he not only suffered from several childhood diseases but also had his tonsils and adenoids removed. To this is added the fact that the mother gave birth to her third child, a girl. The mother's conflict in relation to these two children can be easily visualized—a boy whom she has constantly attended and slept with for five years, who has become ill, and a new born girl child, who because of her helplessness, must have the mother's attention. Charles evidently succeeded in holding his mother in spite of the newborn sister for he continued to sleep with her for the next three years. At about this time, mother became pregnant and then later gave birth to a male child. With the mother's acquisition of a new male lover in this newborn child, Charles was displaced from his mother's bed and made to sleep with his father. The child then began a new series of attempts to regain and hold his mother's love. He refused to dress himself so that his mother continued to dress him until his placement in the institution. This was an overt attempt to return to an earlier infantile period, as his rebellion against mother's pregnancy and later the newborn child. His behavior at home, at school, and in the neighborhood began to take on a more destructive and aggressive nature. Despite this, the mother fully glorified in and enjoyed the boy's notoriety. This was the time when the Bellevue Psychiatric Hospital made a tentative diagnosis of post-encephalitis. With the birth of the child, his behavior became unbearable and he was

placed in an institution where he could receive psychiatric treatment

The abnormality of the home setting and the major role it played in the production of this boy's antisocial behavior were readily recognized by all the agencies that contacted this family. The hospital that continued to treat this boy from August 1927 until his institutional placement, made a home visit to gain the mother's cooperation, but was so discouraged that they made no further efforts in this direction. It however, continued to direct its effort to the personal treatment of Charles. Other agencies that became interested evidently felt the same way about the mother and desisted in their attempts in this direction. It was for this reason that removal from the home and placement in an institution was advised where he could receive psychiatric treatment.

Parental Background

A proper understanding of Charles' problems necessitates a study of the parental background. From the meager information at hand we can deduct the following facts: we note that Mr S completely identified himself with his father. He, as his father before him, was uninterested in the children and home and only concerned with his own pleasures. We note too that at ten he was forced into the role of father and had to work to help his mother support the family. From the expression of the children it seems evident that mother had to play the role of both father and mother to them. Mr S did not have to compete with his father for his mother's love since father had definitely rejected mother. He was mother's love object and filled the place of father. Mr S in his own marital life continued this situation for they were happy until the birth of the children. He felt his wife had rejected him, especially for Charles. He began staying out late at night, playing cards and refusing to take any part in the bringing up of the children.

Mrs S identified herself with her mother who too had to bring up her family without the help of her husband. Mrs S's father had died when Mrs S was two years old. It therefore became necessary for her mother to play the double role of mother and father. Mrs S too had to play this double role in bringing up her own children for Mr S's attitude was that it was the wife's duty to bring up the children and care for the home, he was the provider. Mr S's inadequacy as a husband and lover to Mrs S is expressed in Mrs

S's complete absorption in her children, especially Charles, who slept with her for eight years. We also have a diagnosis of a psychoneurosis on Mrs S from the hospital OPD where she is being treated.

We can definitely see that the birth of the children instead of cementing the marriage bond tended to alienate Mr and Mrs S. The parents were unable to bring about the necessary rearrangement of affection and love called for by this event. Mr S rejected Mrs S and all of his children and sought his love in the outside world, while Mrs S overprotected and infantilized them, especially Charles, finding her love in her children. The reactions of both parents were neurotic.

Our early contacts with Charles plus a study of the foregoing factors made it evident to us that Charles' emotional development had been greatly retarded. He was still a very infantile child who had been overprotected by his mother and upon whom he looked as his personal property. His father he both loved and feared and justly so, for father beat and berated him. He hated his sisters and newborn brother.

We felt that Charles' reactions were protective in nature since they were based upon his feeling that mother had rejected him, that without her he could not hope to live. His being forced to sleep with his father after eight years in mother's bed must also have been accepted as a rejection for he was now at the complete mercy of the father whom he felt hated him. This complete rejection must have mobilized his fears and resulted in his aggressive activities by which he attempted to master his environment and so win back his mother to assure him of safety. These activities we consider adequate for one of his infantile emotional development.

This concept of Charles enabled us to plan his treatment upon his admission in April 1929 to the controlled environment of our institution. The psychiatric social worker's first contact was made with Charles at the reception house where he was tested mentally, his Binet rating was IQ 143. The cooperation of the school principal enabled us to plan Charles' program in accord with his high IQ. A cottage with the proper type of cottage mother was picked to facilitate his adjustment and evolution. Therapy at this time consisted of contacts by the worker about the institutional grounds and facilitating his participation in group activities.

Charles' aggressive behavior rapidly sank into the background. He seemed to have adjusted since he caused no trouble in the cottage or at school. The school reported

excellent progress and regular promotions. The cottage mother felt that he was a good boy, since he gave no trouble. A closer scrutiny, however, showed him to have become seclusive, most of his time being spent in reading or day dreaming. This seeming adjustment continued until the early part of 1931 when Charles, after a visit to the city developed scarlet fever and was removed to an outside hospital. He returned to the institution in April 1931, after three months' hospitalization. Several running away episodes then occurred, but only in the first one did he succeed in reaching home. His mother berated him and immediately returned him to the institution, as Charles said "without even giving him a hot meal." He now became the aggressive and destructive child he had been previous to his original placement in the institution. This necessitated the administration of a more active type of therapy by the Child Guidance Department.

During the early interviews we learned the reasons for Charles' seeming adjustment up to this time. He considered his placement at the institution an additional rejection by mother with a complete loss of her whom he had up to this time looked upon as a necessity for life. Mother had left him, life became an uncertainty, and as a result Charles withdrew himself and became mildly depressed, and it was this which was accepted by the cottage mother as an adjustment since he caused her no trouble.

The institution he evaluated as the hard, cruel, unbending father whom he could not rebel against without fear of punishment. The cottage mother he could not trust for she was identified with his own bad rejecting mother, while the harsh treatment he claimed he received from the first commissioner made him identify the commissioner with his father. In his reading and day dreaming he found an adequate escape in that he constantly thought of himself as the hero who annihilated the villain (father) and married the heroine (mother).

Our re-evaluation of Charles at this time made us feel that we were no longer dealing with a case of conduct disorder but rather a psychoneurosis in which anxiety, aggressiveness, a feeling of guilt, and a tic of the head as in negation were the outstanding symptoms.

At this point one might well ask what forces had produced so marked a change in Charles' behavior. Our material shows the following: the necessary infantilization during his prolonged illness plus mother's concern made him feel that he

has recaptured his former position of dominance in his family. As a result upon his discharge from the hospital and return to the institution he absconded only to find himself rejected by mother. Charles' prompt return to the institution by his mother must have been a shock, something he could not reconcile with anything in his past experience. Previously when ill mother had given him protection and love. He could not understand what had happened, and as a result anxiety made Charles react in the only way he knew which was by attacking. Charles felt himself exposed to an external danger, and in addition his narcissism had been injured. Charles' state therefore approximated that of a helpless child. Under such a sudden and violent transition the whole psychological structure loses its rigidity. This accounts for the sudden change of behavior from one extreme to the other where one group of feelings was replaced by another almost exactly the opposite.

Charles was taken on by the Child Guidance Department for active therapy, the worker was instructed to see the child every second day for one hour. Charles being a talkative and aggressive child, he was instructed to give his associations freely. The worker was to assume a friendly but detached attitude to the boy's associations. This friendly though detached attitude was supplemented by more active evidence of interest in Charles. He was helped with his school work, he played an occasional game of checkers with the worker, and was stimulated to take part in extracurricular activities about the institutional grounds.

Charles rapidly developed a compliant attitude towards the worker, and readily produced historical material, fantasies and dreams in which he expressed his overt fear of his father and sister whom he felt hated him and wished to separate him from his beloved mother. The mobilization of his fear of death, which the loss of mother meant, caused him to become aggressive and so to overcome the threatened danger in his environment. Charles was at this time expressing this same conflict in the cottage and school and attempting to solve it by his hyperactivity and aggression towards everyone. Great tact had to be exercised by the worker to gain the continued cooperation of the cottage mother and school teachers for Charles was very trying. In the interviews we had evidence of a growing attachment to the worker.

Transference manifestations soon appeared in the interview in which the worker was identified with mother with the ex-

pression of marked ambivalence and with father on a hate basis—Charles at this time expressed a death wish against the worker. The interpretation of this death wish on a transference basis caused a negative phase to appear. This resulted from so deep an interpretation being given too early in the treatment. His ego was not strong enough to accept such an idea in consciousness, so that it had to be repressed. His anxiety as expressed at this time was evidence of a mobilization of his fears, for he felt certain that he would be annihilated.

This impasse necessitated the use of a technic we have found most valuable in gaining the child's cooperation. It was evolved by Miss Julia Goldman, former head psychiatric social worker, now Executive Director of the Institution, and consisted of allowing the child to play the dominant role while the worker, pretending to be tired, reclined upon a couch. Charles soon became solicitous and inquiring, and before long assumed the role of a parent, revealing to the worker many long repressed difficulties. With a rapport thus established, and still in the recumbent position, the worker found himself able to ascertain and discuss freely many of Charles' long-suppressed difficulties, this in spite of Charles still retaining the parental role. This rapport then enabled the worker to continue the analysis by means of play technic.

Charles in his activity with the toys, worked off his aggressiveness in playing at destructive warfare. On other occasions he played house and helped mother raise the family. A change was noted in the boy's attitude towards institutional life. He became friendly and cooperative in the cottage and in school so that he was elected president of his class. He entered into institutional activities and excelled, winning many prizes for his cottage. He also became friendly with a girl and was pleased with the friendly attitude of the other children towards him. Charles had now ceased to be a problem in his institutional environment. Formerly he had acted out his conflicts in the outer world, but now this had ceased and instead took place in the therapeutic situation with the worker. These conflicts Charles expressed by historical production from infancy and childhood, in fantasies and dreams of his great powers and by acting out old love and hate situations by the use of toy materials.

A new phase had supervened in the treatment, the worker had now become identified with Charles' parents and Charles transferred on to the worker all of his in-

fantile strivings, his loves and his hates. This was the "transference" and the worker utilized it for the boy's good.

A new element entered when Charles' parents asked for his return home. We feared to allow this since we knew of the obstacles that had been encountered by all the agencies that had attempted to contact the home, before Charles had had to be removed to the institution. We were also aware of the fact that Charles' insight was superficial and that he was still a dependent child and in need of parental love and protection. In spite of our advice to the contrary Charles was discharged to his parents in October 1933.

For the first three months following Charles' return to the home, he was accepted into the world from which he had previously been rejected. His sister became jealous of the attention he was receiving and accused him of hitting her. Mother entered the picture too and once more tried to reduce him to the position of being her beloved baby. Upon his refusal and rejection of her she beat him and accused him of beating her. This increased father's wrath against him and finally led to actual fist fights between the two. He again became the talk of the neighborhood and played truant from school. The mother complained to the school and a conference was held at which the boy begged to be taken to court and returned to the institution. Charles was readmitted to the institution in June 1934, nine months after his discharge.

A period of maladjustment within the cottage followed his return to the institution in which aggressiveness was most marked against the cottage mother, and the other children. However therapy soon removed this to the analytic room and the interviews became the place for explaining his aggression and the worker the recipient. He once more proceeded to work through his hate for his father, mother, sisters, and brother with a great display of emotion and evident emotional insight. He was able to understand and interpret the material he produced and see the transference identifications. With the gaining of this new and deeper insight, his anti-social behavior ceased entirely both in and outside of the interview. He realized the futility of attempting to master his environment through aggression and destruction and began to face his problems and react adequately to them. He became the model of institutional adjustment in his cottage, on the grounds and in school.

The psychiatric worker in addition contacted the family and did intensive work

excellent progress and regular promotions. The cottage mother felt that he was a good boy, since he gave no trouble. A closer scrutiny, however, showed him to have become seclusive, most of his time being spent in reading or day dreaming. This seeming adjustment continued until the early part of 1931 when Charles, after a visit to the city developed scarlet fever and was removed to an outside hospital. He returned to the institution in April 1931, after three months' hospitalization. Several running away episodes then occurred, but only in the first one did he succeed in reaching home. SEPTICEMIA FOLLOWING ACUTE SINUSITIS TREATED WITH SULFONAMIDE COMPOUNDS

J COLEMAN SCAL, M D , F A C S , *New York City*

From the Otolaryngological Service of Dr S J Kopetzky, Beth Israel Hospital

Recovery

Sulfanilamide, Para-Amino-Benzene—Sulfonamide, (Prontylin) and Azo-Sulfonamide (Prontosil) have been in use now for practically three years. The remarkable results obtained certainly warrant its use in any streptococcic infection. Its action is derived from its ability to inhibit the growth of hemolytic streptococci by its apparent bactericidal effects on the blood. This is accomplished by stimulating phagocytoses to such an extent that they easily inhibit or destroy the streptococcus.

In the following case reported azosulfonamide in the form of Prontosil and para-amino-sulfonamide in the form of Prontylin were administered, the former intramuscularly and the latter by mouth

Case Report

M G, female, age forty-two, practical nurse by occupation. Family history irrelevant. Past history negative except for a nasal operation performed fifteen years ago. Present illness dates back to twelve days prior to admission to Beth Israel Hospital when she had been ill with cough, headache, temperature of 101° F, and nasal blockage and discharge. Two days later she developed an O.M.P.A. in the left ear and a paracentesis was performed. The acute upper respiratory infection had grown progressively worse until January 17, 1937, when she was admitted to the hospital with temperature of 104, frontal headache, nasal discharge together with profuse aural discharge from the left ear.

Examination of the nose at this time revealed both nostrils filled with pus, the mucous membrane congested and swollen, and the nose completely blocked. The right ear was normal but the left showed a perforation in the lower posterior quadrant which was discharging freely. There were no mastoid signs or symptoms.

Treatment consisted in adrenalization and gentle suction of the nose at frequent in-

tervals, inhalations of Tincture of Benzoin Compound and instillation of boroalcohol drops in the discharging left ear. The night following admission the temperature rose to 105° F and was followed by a severe chill with a drop in temperature to 99° (Chart I). A blood culture taken immediately showed three colonies of streptococcus hemolyticus per c.c. increasing to twenty colonies in the culture taken five days later (Table I).

The blood picture showed the red blood cells gradually decreasing from 5,000,000 to 3,000,000 and the hemoglobin from eighty-two to seventy-two per cent. At the height of the infection the polys and staff cells were very high. There were thirty staff cells with a poly count of eighty-eight and a great number of toxic polymorphonuclears the day after the first culture. The temperature fluctuated from 100 to 105° becoming normal on February 22, and remaining so until date of discharge.

X-rays taken on January 18 showed the frontal sinuses undeveloped while both antra, the ethmoids, and sphenoids showed an inflammatory involvement, more pronounced on the right side. The mastoid cells were of the small pneumatic type with no destructive changes present. X-ray of the lungs showed no pathological condition except for some slight thickening of the pleura of the left base. Further x-rays of the sinuses taken on February 2 showed the frontals rudimentary while all other sinuses were involved by a suppurative process.

Nasal treatment consisted of puncturing and washing the right antrum, suction of the right sphenoid and gentle suction of the nose followed by ephedrine instillation and short wave treatment.

On January 21 a complication occurred in the form of thrombophlebitic-metastasis of the right wrist. The wrist became swollen and painful and Dr Harry E. Isaacs was called in consultation. He said he believed there was probably some bony destruction present in the carpus which accounted for the severe pain. He suggested immobilization with a splint and later a plaster cast.

The aural infection present in the left

with them. At the end of ten months we felt they had developed sufficient insight for a partial change of attitude. This plus Charles' new insight made us feel safe in once more discharging the boy to the home, where he has continued to adjust.

It is self-evident from this case history that the family pattern of these parents played the major role in the production of this boy's behavior problems. The mother's intense and continuous infantilization of this boy prevented him from making the necessary adjustments to his environment. His instinctual urges persisted in their original state up to his eleventh year and were expressed in his overt destructive behavior against his environment. There was no necessity for him to live through an Oedipus conflict for there was none, he was mother's husband and slept with her

Father had willingly left mother to him. As a result the latency period was greatly delayed and only made its appearance with the production of the necessary identifications and sublimation while under psychiatric treatment. The psychiatric treatment gave this boy an opportunity of overcoming in part his faulty environmental development. He was given the opportunity of reliving some of his many conflicts and helped to solve them on a higher, more acceptable social plane. He was provided with adequate ideals to replace his own inadequate neurotic parents. This allowed him the necessary means of identification as well as the means of living through in fantasy a normal Oedipus conflict and to establish the latency period with the necessary sublimations.

667 MADISON AVE.

SERUM IN PNEUMONIA

That the physicians of the State may have concrete examples of different phases of anti-pneumococcus serum treatment of pneumococcus pneumonia, there will appear here case reports selected from the large number received by the State Department of Health on the use of anti-pneumococcus serum produced and distributed by it.

In order that physicians practicing in New York City or those using effective serum from other sources may also be represented, we hope that physicians who may have had particularly significant experiences with serum will submit short reports to the Pneumonia Editor, New York State Journal of Medicine, 33 W 42 Street, New York City—Editor

Case 8—Incorrect Use of Type I Serum

Report from the records of the Meadowbrook Hospital by George Jaspin, M D, Department of Pediatrics, Hempstead

A D white male, 8 years old, admitted with a story of sudden severe, right chest pain, fever and vomiting twenty-four hours before admission.

He was admitted at 8.20 P M and physical signs of early pneumonia in the right chest were found. Temperature 104.2, pulse 130, respiration 30. Typing revealed a few Type I pneumococci.

He was given 6250 units of type 1 State antipneumococcus serum at 10 P M, 10,000 at 3 A.M., and 10,000 at 8 A.M. The temperature rose to 105 by 8 A.M.

The patient was retyped and many Type V's and a few Type I's found.

The patient was then given Type V

Lederle Serum U10,000 and the temperature promptly fell to normal and stayed there.

X-rays taken two days after admission revealed right upper lobe pneumonia.

The above case illustrates an interesting point regarding the administration of anti-pneumococcus serum. The symptoms of only twenty-four hours duration favored an immediate response to Type I serum, which was not noted in this case. A retyping then showed a Type V pneumococcus.

In such cases where a definite improvement is not shown to Type I serum, the fault may often lie in attributing the etiology to a Type I organism instead of the correct one. It has been our procedure to retype any case where the response is not definite and the organism is usually found to be other than a Type I.

CASE RÊPORT—SÊPTICEMIA

June 15, 1937

ear cleared up by February 20 at which time the perforation of the drum was closed. No pain could be elicited on pressure over the mastoid.

Consultations were held with Dr S J Kopetzky who did not find the paranasal sinus infection sufficient to account for the character of the temperature, the chill, and the increasing staff cell counts. Dr L Friedfeld suggested that the symptoms indicated a thrombophlebitic condition without localization of the focus. He ruled out the chest findings as not sufficient to account for the present symptoms. Dr A. A Epstein was in accord with Dr Friedfeld's findings.

Treatment with the sulfonamide compounds were commenced on January 19 when five cc ampules of Prontosil were administered intramuscularly twice daily and Prontylin tablets of five grains each

were given by mouth every three hours. This treatment was continued until the patient's temperature reached normal. It was discontinued on February 20. At the time of discharge on March 4, the patient's wrist was improved but she was referred to the Physiotherapy department for further treatment. The left ear was entirely healed and the sinus involvement cleared up.

Conclusions

While this chemotherapeutic agent is being tried and exploited it should be borne in mind that it is not a specific for streptococcus infection. Sulfonamide compounds do not act directly on the organism but in some way influences the action of the body so that it produces a

look other symptoms which, on thorough examination, will prove to be those of a pulmonary process or cardiac disease. One may find some definite metabolic disturbance, diabetes, or arthritic changes where one expects them the least. Or the complaints are related to bad habits in sleeping, eating, and drinking. Or there is overwork.

In somatic cases a thorough search may clear up the cause, although it may be of partial help only in curing the patient's mind. In psychosomatic states, where the physical etiology is difficult or impossible to establish, the patient must be treated as a neurotic, attempting whether we want to or not, at the same time to correct his living errors. But even where we are certain that the condition is entirely mental or psychological, we cannot dismiss the patient—and he is ubiquitous, he is legion—as a “crank,” or tell him he is “only nervous.” Nor should we blame him for our incompetence. This will never solve the problem. In the first place he will remain unconvinced and doubt the doctor's ability. And, he will have the right to ask “Why not do something for my nervousness, then?” Or “What am I to do for my ache, or burning, or depression, or restlessness—real or unreal?”

The accident, near accident, or the healed sickness has left an imprint. It has released something that was latent, unknown and hidden. It has changed the well adjusted individual into an unadjusted person. It has made him unhappy, or as the case may be, rather happier if he enjoys his complaints and the attention he gets, and feels comfortable in this situation.

All illness makes us more selfish. In proportion to its intensity it separates us from the world. But adequately balanced—that is, optimistically inclined—the mind disregards and suppresses a good deal of physical ailing and limits its effects, so that emergence into a cure is possible and the joy of living accelerated again.

We may safely say that a *physical sickness is not cured until it is mentally healed*.

The pessimistic mind holds on to illness after it is gone. It throws a long shadow or a penumbra, from which the patient cannot or will not come out. He is tuned up to illness, he is inebriated with it. Inertia keeps him in it. Is not persistence in a state of rest or motion, unless checked by some force, a universal law? Why can we understand the continued production, and sometimes detrimental overproduction of bone tissue after a fracture, and not the mental disorder of the realm of a post-malady? This disturbance does not necessarily indicate a sick mind, but a mentality

full of ideas of sickness. Perhaps the word *nosopsyché* would describe it if the “soul” were not so vague, so loose a term, especially with its ancient, unscientific implications. *Nosopsyché*, sickness-mentality, is better.

A carpenter, large, powerful—“so strong,” he was described by an informant, “you couldn't kill him with a mallet”—fell from a scaffold but was not injured, which he could not believe. After many changes his complaints finally settled to epigastric pains. He had been examined and re-examined in institutions and by private physicians. He knew all the hospitals, and the gossips about them and the most famous doctors of the city. He was familiar with medical terms and looked with contempt upon any young interne who dared to ask him questions about his symptoms. From a diligent, responsible, self-supporting worker, he degenerated into a shiftless beggar living from his friends' alms and spending one night here and one night there. When this examiner saw him, the patient slept on the hard bare counter of a relative's store. He respected surgery, and for months insisted that he needed an operation until he succeeded in fooling a surgeon into an exploratory intervention, which revealed nothing. From then on the patient, proud of his scar, showed it to all of his acquaintances. His complaint, however, was the same as before. During our conversations, I learned that some time before his accident he was repudiated by a girl he loved. She married somebody who died long ago, but she remained a widow. He was advised to go and see her. At first incensed, he later agreed to my suggestion, and after various events she accepted him, and his problem was solved. He was cured and really metamorphosed into his former self.

A bookkeeper, who being unemployed had to work in a CCC camp, claimed to have been mistreated and beaten up by the boys. The camp doctor gave him some hypodermic injection. Since then he had “two kinds” of attacks,” one of unconsciousness and one of precordial pains which he claimed occurred at different times. They were treated separately, although they really belonged to the same condition, hysteria, the “pain” being the preliminary symptom or a sort of aura. Hypnotism, electric shock, the entire neurological-pharmaceutical-armamentarium, the whole gamut of physical therapy were administered. No result. No improvement was seen from a treatment for angina pectoris. Bodily, he was well but questioning revealed that he suffered from a sickness-

phagocytosis of streptococci in a few hours after administration and the blood assumes a strong bactericidal power

The dosage of Prontosil in a five cc ampoule can be injected intramuscularly three times daily. In extreme cases and in obese patients ten cc can be used with impunity. Prontylin tablets can be given at the same time to supplement the Prontosil. One or two tablets given every four hours are sufficient. The dosage should be reduced and the interval lengthened as the patient improves.

These compounds are quite safe in administration to humans as the toxicity is very slight, the dye appears in the urine

in about ten or fifteen minutes and stains it red. The only ill effects that have been reported are some renal irritation in the form of albumin and some epithelialized red blood cells as well as nausea and faintness. Saline laxatives should not be given during the administration of the dye. Overdosage and long continued administration may result in mild jaundice.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D, D R P H, *New York City*

Editorial Note: Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Nosophrenia

It is well known that after accidents, whether followed by injuries or not, some patients remain with a mental trauma from which they cannot recover. The situation is worse when complicated by trials and litigations.

But a similar condition develops in certain people after a physical illness, even after a complete cure. The somatic pathologic state, although temporary, has had the effect of injuring the mind of the patient who undoubtedly was neurotically predisposed, or whose life forced him to subconsciously get hold of an excuse for a neurosis. Very often the condition is so little of a disease that it does not deserve a name and it cannot be classified anywhere. It is not a true, rounded-out psychoneurosis, although it may belong as it were, to a sub-section of the latter. It is a slight transition case but by no means transitory, and it spells a great nuisance to both the patient and his immediate environment.

Just as the person who has fallen from the train and who cannot point to any injury, will not believe that nothing has happened to him, so the same type of indi-

vidual remains in doubt as to his healing after an acute sickness. Perhaps, after all, such patients are not entirely wrong. The body may be all right, but the mind may have been wounded. Why do so many men, after their return from the battlefield or trenches "without a scratch," suffer from no other consequences than that of just having been in the fire close to danger and death? Is not fear, fear of anything, whether based on true or imaginary facts, an important trauma or a factor in causing a mental trauma?

Of course, we have the hypersensitive person and the perpetual complainer who will be excessively frightened by any unpleasant event in their lives, or who will unduly exaggerate some real trouble.

It is not always easy for the physician to determine whether organic pathology is present or not. The very behavior and attitude of the patient may mask something very important. We should not judge him from mere appearances or impressions. He may persistently complain of some general vague aches, perhaps with an accentuation in the chest or dorsal region, and over-

EDITORIALS

William A. Groat, President-Elect

At the recent meeting of the House of Delegates, Dr. William A. Groat, well known physician, clinical pathologist and educator, was elected to the position of President-Elect.

He graduated from Syracuse University College of Medicine in 1900. His advance in his chosen field was rapid and his contributions to medical science and medical literature have received international recognition. He entered the World War as a captain in the U. S. Medical Corps and was discharged from the Army at the end of the war as a major, and since 1921 is a lieutenant colonel in the U. S. Organized Reserves.

His manifold activities are shown by his appointment by Mayor Forbes of Syracuse to the secretaryship of the Syracuse Public Health Committee of which he subsequently became chairman.

He has been president of the Syracuse Academy of Medicine, the Central New York Medical Association and he presided at the Fifth District Branch Meeting of the Medical Society of the State of New York. He served a long apprenticeship in the State Society under the chairmanship of Dr. Thomas P. Farmer on the Committee on Public Health and Medical Education. He has been Chairman of the Committee on Scientific Work since 1933.

Thus another man has been elevated after long apprenticeship and work for the State Society. We congratulate Dr. Groat upon his election and look forward a year hence to his assuming the presidency with confidence that the great traditions of the past will be continued under his leadership.

Social Security Upheld

In the short time since the Supreme Court's affirmation of the Social Security Act, a strong movement has developed to extend its benefits to millions now exempt. What effect will this have on the prospects of compulsory health insurance?

In "Social Security," Maxwell S. Stewart, an outspoken advocate of social legislation, frankly admits that "insurance" in the true meaning of the word is not the goal. "Insurance not only implies the

impractical actuarial approach but may be easily used as a pretext for placing the entire cost of security on the underprivileged."

This is confirmation, from an unexpected quarter, of an argument that medicine has repeatedly advanced. Since compulsory health insurance is actuarially unsound and the worker overpays for what he receives, why preserve the pretense of an insurance system? In practice the

psychology due to a great frustration, a deep disappointment in his younger years. The facts that had led to his present condition were analyzed one by one and he was shown how foolish it was to let them mar his life. Then the attacks began to weaken, and although so far they have not disappeared, they have diminished much in frequency and intensity.

A young lawyer had an appendectomy performed, but as the trouble was elsewhere he was not cured. He suffered from headache and somnolence, and nobody seemed to make the right diagnosis or to find the proper treatment until one physician suggested some plain therapeutic measures that cured the patient as far as his symptoms were concerned. He entered, however, into a new phase of his illness. His mind refused to accept the cure. He somehow felt that his sickness was unfinished, first, because the treatment was modest and not spectacular, and second, because as he said "it was too good to be true." Only after being shown convincingly, in several sessions, that there was no disease and that he had remained in a mental state where sickness was a sort of necessity, did he understand his condition and consider himself healed.

A woman, otherwise in good health, suffered from a series of boils, a mild furunculosis, until she was well and stayed well. This, however, did not satisfy her. She feared that her blood was "unclean," which led her to other complaints and to suspicions of diabetes, cancer, and so on. After these were dispelled she claimed to suffer from "difficulty in swallowing," "her eyes were bulging out," "her pulse was rapid," and "she had an internal goiter." The truth of the matter was that she was close to fifty, her children were of an age when they did not need her, and she had nothing to do. She was unhappy. When she improved, I thought that was due to my treatment but I was mistaken. Meanwhile her husband had had business deficits and had to open a very small store without outside help where our patient's services were in demand. Now she was busy and useful, and she forgot her complaints. The economic depression had cured her personal depression.

Another patient broken down by the depression, was a magazine illustrator with

no orders. He was too proud for cheap and uncongenial work. At the first occasion he became nosophrenic (sickness-conscious). He had a pain in one sole due to callosities. He was sure, therefore, that he suffered from endoarteritis obliterans, about which he had read. He began to limp and refused to go out of the house. Meanwhile he and his family became poverty-stricken and were dispossessed. But nothing could change his convictions until he was persuaded to swallow his pride and to work as a commercial draftsman. As soon as he was able to make a living, he was mentally well. For a time his case was similar to the more celebrated American landscape painter Blakelock, now dead, who starved with his large family, and whose recognition came too late, when in an institution for the insane.

A woman had an appendectomy, and her surgeon told her afterwards that the operation had been unnecessary because the appendix was found to be normal. Of course, we owe our patients the truth, but once an error has been committed it cannot be repaired by another blunder. The surgeon should have been extremely careful in the first place, but if he failed he should have kept the secret to himself. In the case at hand he had to deal with the kind of patient who could not withstand the shock of confession. She developed a general fear of disease due to the lack of her healthy appendix and was sure that her future children were doomed. The psychiatric dispensary where she went, did not help. The two doctors assigned to her case in turn, provoked no transference or even simple confidence. One was a newly immigrated foreigner whom she could not understand. The other was an incompetent beginner in psychiatry. (And by the way, these transition cases coming to out-patient clinics deserve specialists with at least as much training as the experience of the inside workers.) As a result this patient was even more alarmed, "not even the men to whom I have been sent can cure me," she said. Only with the greatest difficulty and after the birth of a healthy baby, the conception of which was advised by the examiner, was she cured of her fears and anxiety.

. . .

Truth is relative, and under certain circumstances, harmful. When exaggerated in someone's mind, it becomes a lie.

611 W 158TH ST

of economic and educational opportunity, who will make the new discoveries that promise so much to surgical safety and comfort?

Anesthesia is still in its infancy. To realize its tremendous potentialities, requires the devoted, enthusiastic service of skilled practitioners. Today able men are discouraged from entering the field by the trespassing of nurse anesthetists, who compete on the basis of lower pay to compensate for their inferior qualifications.

Advances in anesthesia are an important factor in surgical progress. The future of surgery, no less than of anesthesia, demands that practice of the latter be limited by law to trained physicians.

Provision for Medical Care, Principles and Proposals

We desire, at this time, to call attention to the Report of the Special Committee to Consider Provision of Medical Care which was recently adopted by the House of Delegates of the Medical Society of the State of New York.

Both the principles and proposals with their qualifying clauses, and the Report of the reference committee to which they were referred are to be published in this JOURNAL. The recent meeting was so fruitful of many things, particularly as regards progress in paramedical affairs, that we will reserve comment on these matters to some future time. At the present time we desire only to call attention to their publication in the next issue.

Speaking of Diet

There has been thrust upon us, within our memory, the importance of realizing that what we eat may, and perhaps does, influence the comfort and duration of our sojourn on the planet Earth. The nephritic, the diabetic and all the other "ics" can prolong their stay by a strict adherence to a nutritional régime abounding in sacrifices. On the other hand, the tuberculous, the scrofulous and their allied "ouses" strengthen their toe-hold by indulging in a veritable orgy of foods.

What of us who belong to neither the "ics" nor the "ouses"? It would seem that even though we are up-and-about, we must take heed lest what we put into our stomachs does not impair, retard or in other ways modify our efficiency as members of the human race. According to Lusk¹ "carbohydrates are the most economical of foodstuffs, both physiologically and financially." Pollack and Dolger² tell us that mechanical efficiency is greatest with a high carbohydrate diet, and state furthermore that "a high protein diet is a luxury and in times of economic stress is an unnecessary indulgence." Heil, somebody.

But we want steak, preferably fillet mignon. If we can't have steak, any of the other proteins on the menu will provide an acceptable second choice. And economic stress be damned as long as hot-dogs and hamburgers are available to the protein-minded for a thin dime, a tenth part of a dollar.

However, the spirit of compromise tempers our belligerency. Having vented our spleen, we now feel like the millionaire who entertained his impoverished friend during an evening repast at his home. The poor devil, seeing his rich host served by his butler with a sumptuous steak, started drooling at the mouth. With the passing of time and hunger having conquered his better manners, he anxiously inquired—"Are you going to eat that steak alone?" Whereupon his monied friend replied, "Of course not! I'll eat this with potatoes!" And that's what we call a balanced diet!

CURRENT COMMENT

"* * * THE PROPONENTS of sickness insurance are social uplifters, or job perpetuating politicians, idealists, pseudo intellectuals or theorists who would wreck a nation in furtherance of a theory, even if it took a thousand years to prove they might be correct—or wrong * * *

"Has the State ever shown anywhere that

¹Lusk, *Science of Nutrition* 4th Ed., 1928

²Pollack, H., and Dolger, H. *N Y S J Med*, 37, 633 Apr 1, 1937

latter has always proven to be an excuse for an unnecessary, expensive bureaucracy and a cloak for political domination of medical practice

Once we frankly acknowledge that medical care for the indigent and near-indigent is a responsibility of government, the way is clear for consideration of the means of furnishing this service without recourse to the deceptions and fallacies of compulsory health insurance. The Medical Society of the State of New York has taken the lead in an attempt to formulate the principles of a suitable public health policy and establish cooperation with the governmental agencies concerned

Responsible public officials realize that compulsory health insurance would necessitate oppressive taxation without commensurate benefits in return. They have begun to understand that no system of medical service can promise success over the opposition of the medical profession. If, in spite of this knowledge, some of them have lent a responsive ear to propagandists for obligatory pre-payment, the failure of physicians to take an aggressive stand has given them an excuse for yielding to political pressure.

The action of the Medical Society of the State of New York at its recent Annual Meeting has taken away that excuse. It announces the determination of organized medicine to establish a public health policy which recognizes both the medical rights of the under-privileged and the economic rights of the private practitioner.

John D

The medical profession of the entire world is deeply affected by the death of John D. Rockefeller, senior. By his foresight and action, the peoples of this earth have been relieved of many of the pestilential diseases which wrought havoc among them. His generosity was responsible for the creation of the one outstanding force to combat the scourges which from time to time, descend upon us. Most of these, through the agencies he endowed, have been conquered.

Space does not permit us to itemize the innumerable accomplishments of the Rockefeller Institute, nor is it sufficient in scope for us to enumerate the distinguished medical men who so nobly gave of themselves that an ideal might be accomplished. Unhindered, unchallenged, and free to carry its work forward to even greater glories, the Rockefeller Institute will ever stand as a tribute to a great humanitarian.

Looking Ahead

The valuable studies in anesthesia presented at the Annual Meeting of the Medical Society of the State of New York justify the profession's demand for limitation of this branch of practice to qualified physicians. The constant discovery of new drugs and adaptation of old ones to produce or aid in the development of anesthesia, demand informed, discriminating medical opinion to sit in judgment.

It is not enough to know how much of a particular substance is commonly administered and by what technique. The skilled anesthetist must understand the effects of the drug he is administering on all the tissues of the body. He must be able to gauge the individual patient's response and detect the earliest signs of distress. If the anesthesia is borne poorly, his medical knowledge and ability must make up for the patient's constitutional weakness. A nurse, no matter how well trained, is not equipped for these onerous responsibilities.

It is not merely the present but the future of anesthesia that the growing encroachments of the nurse anesthetist threaten. The field of anesthesia is necessarily a limited one. If nurses usurp the employment opportunities of physicians in routine cases, how are skilled specialists to be developed for difficult ones?

Scientific progress in anesthesia has hitherto resulted, and can continue to result, only from the experience and research of medical men working in this field. If the development of creative specialists is prevented by the curtailment

Neither Suggested nor Implied!

20 East 76th St
New York City

To the Editor—

In the May 15, 1937 issue of this Journal in the section devoted to correspondence, certain exceptions were taken to our recent review on protein requirements. The criticism was based upon a misinterpretation. It was not our purpose, (nor did we even intimate such an idea) to advocate a universal diet of 60 grams or less of protein daily for all people under all conditions of health or disease. We did not even remotely suggest by word or implication that high protein diets are not indicated in nephritis associated with hypoproteinemia. It was emphasized however that the ingestion of 60 grams of protein daily was sufficient under normal conditions to maintain nitrogen equilibrium. It was further inferred that the choice of a high carbohydrate diet by those on limited budgets was a happy one because of the definite and well known protein sparing action of this type of food-stuff.

During the past three years we have had occasion to see about 1500 patients of this class in the nutrition clinic. About half of these have been on "relief" for this period

of time or longer. Our problem was to instruct them to spend their money most efficiently. These people could not purchase a uniformly high protein diet because of limited funds. We accepted the standard of approximately 60 grams daily from the classical, time tested work in the field. Never once in this series have we observed the occurrence of nutritional oedema or other evidence of hypoproteinemia or the development of any other form of nutritional deficiency. The attendance in clinic did not vary even during the severe seasons when upper respiratory infections were prevalent. It was our impression that these people were not any more susceptible to infection than the general run of patients. Random hemoglobin in determinations and red blood cell counts have not shown the development of anemias. The only instance of nutritional deficiencies we observed were in post-operative feeding cases and among a few food "faddists."

Dr Bridges has read implications into our article which are quite unjustified by content.

HERBERT POLLACK, M.D.

HENRY DOLGER, M.D.

May 29, 1937

CHANCE FOR MORE NEGRO DOCTORS

A glittering opportunity for colored physicians is seen in the fact that for each 4000 Negroes, there is only one Negro doctor—which gives young men of the race a wide field for leadership and service. That advice was given at the fifth annual

Capital District Vocational Guidance Conference in Booker T. Washington Center in Albany in April by Dr. W. Adrian Freeman, secretary of the Manhattan Medical Society and staff member of Harlem Hospital.

GREAT HEALTH CONGRESS AT THE FAIR

Plans are being made for an International Health Congress during the New York World's Fair in 1939. This has been announced by Dr. Donald B. Armitstrong, President of the National Health Council. Advantage will be taken of the fact that hundreds of noted medical specialists and public health authorities, representing many countries, will be visiting New York City. American

and foreign specialists will be asked to deliver addresses on subjects of interest not only to professional groups, but to the general public.

The more you practice what you know,
the more shall you know what to practice
—Jenkins

it is capable of practicing scientific medicine? Perhaps they will tell you that under state medicine quacks, nostrums, and medical folly would be decreased. Instead, experience shows that these charlatans multiply under state system of control because the people, dissatisfied with what their government gives them, seek out the quacks in search of that personal consideration which all government systems lack." Another barrage against the same old foes, this time from the *Los Angeles Medical Bulletin* of recent date

WRITING OF THE TRAGIC STORY of the great dancer Nijinsky, "who was diagnosed as a schizophrenic by the psychiatrists Bleuler, Wagner von Jauregg, Kraepelin, Ferenczi, Freud, and Jung, (and) is now dreaming his dreams in the Bellevue Sanitarium in Kreuzlingen" the editors of *Medical Record* wonder if, perhaps "In a society differently ordered, could this splitting of a mind have been forestalled? Could the principles of mental hygiene have preserved this instrument of beauty which now is so utterly wrecked? Or is it inevitable that beauty which begins in suffering must end the same way?"

"* * * WHATEVER THE COST, the medical profession must proceed with its education of the public. Until such time as the public understands and accepts the basic truths of medical science, so long will quackery flourish. Undoubtedly there always will be those who believe in the impossible. For their safeguards should be set up by law." From the May Supplement to the *Bulletin* of the Medical Society of the County of Monroe.

"IT IS OUR BELIEF that these two volumes of American Foundation Studies on 'Ameri-

can Medicine' are, thus far, the most valuable contributions on the subjects discussed, and that they will be studied and referred to when other reports of much greater length, but containing the outpourings of theorizing laymen will have been almost forgotten, except for some of their statistical information

"Fact-finding studies and surveys have been much the vogue in recent years, so much so, that most folks are apt to view with suspicion many such efforts. Here in California, the sad experience of spending some \$35,000 of the California Medical Association's funds, under instructions from the House of Delegates, is still too vividly near not to make us share with others the mistrust concerning the value of some of these so-called surveys. For our part, we believe that, had the two volumes on 'American Medicine' been off the press at the time the California Medical Association embarked on its survey adventure, some three years ago, and had the House of Delegates ordered the purchase, and given to each member, for his own library, the two volumes on 'American Medicine,' then our Association would have had, for less than half the money it expended, twice or thrice of what we shall ultimately receive in either value of satisfaction from the California Medical-Economic Survey * * *" Additional words of praise for a splendid piece of work, voiced by the editors of *California and Western Medicine*, May, 1937

"SOCIETY HAS GOT TO PASS toward some better equilibrium, and the distribution of wealth has doubtless slowly got to change. But if any of you expect that such changes will make any *genuine vital difference* on a large scale, you will have missed the solid meaning of life, which is always the same eternal thing—the marriage, namely of some ideal with some courage and endurance." William James "On Some of Life's Ideals"

BOOST, DON'T KNOCK

You know how anxious some people are to open up a discussion which involves criticism of your confreres and how easy it is, by word or by acquiescence, to chime in with it. When we do this we do ourselves and our profession no good and afterward we have that uncomfortable feeling that we have surrendered to expediency and thereby failed to live up to the best traditions of our calling. I think the sum

total of our happiness in life will be greater if we make use of such occasions to come to a diplomatic defense of the profession as a whole, for we know only too well that the fortunes or misfortunes of medical practice are often regulated by factors over which we have very little control. The streptococcus is deadly, whether in our competitor's practice or in our own—B J Gallagher, M D, *Minnesota Medicine*

to chicanery or resorted to competitive standards of cheapness to attract patients to themselves, that when suspicion and envy, and disloyalty and hate, thrived among its confederates, the dignity and honor of the noblest profession was lowered, and with these went the surrender of its survival values. Yes, those old-timers knew, and wisely, that when we no longer adhered to the ideals and medical ethics, conceived in our forefathers' minds, given birth to live in the lives of their successors, society will hold us in disrepute, and in its wake we will blindly follow to self-destruction.

Don't ridicule or scoff because of the thoughts I dare express. The allegiance of medicine and society will ever remain perhaps known by a different name but always "preventive and curative" in purpose—shifting, drifting, continually advancing until life's end.

The profession's greatest fear is its traitors within, a greater menace than our enemies without. You can't evade or elude truth.

May I state that economics in its relation to medical ethics challenges your right to survival as individual physicians, practicing your art unfettered? Society, as a whole, is indifferent to your vibrant protests, not entirely without justification, and scheming politicians and legislators, abetted by social reformers, rejoice at your discomfort, hoping by ruse and misleading propaganda to so mold public thought that eventually the State will take over the control of medicine and direct your activities as physicians. While you growl and howl, they insidiously work. State medicine must not come with its standardized impersonal production methods to sever the personal and confidential relationship between physician and patient in order to achieve the optimum results in treatment. Socialized medicine must not come to retard the progress of scientific advancement in our America. However, I question whether society really appreciates the many sacrifices made in its behalf, or makes a tangible impression. Society likely regards it as just "tough luck" if you selected a vocation unsuited to your make-up, or one that doesn't bear the fruits you expected it to yield. Don't squawk or complain to society—it leaves a squeamish feeling, much to the delight of medical reformers. We can prevent State medicine becoming a reality

if there is unity, loyalty, and faith in well-organized medical societies, and by having able representatives go before the American people, speaking in clear understandable language, recounting the History of Medicine, citing proof of our capabilities to preserve unto them the protection and the best medical care available today, and they should also acquaint society with the high standard of medical ethics we aim to maintain.

The world knows that man is naturally lazy. Unfortunately society thinks the physician is no exception, especially when asked to make a call during the night. Society, as a whole, is as intelligent as you. It observes your attitude, senses your feelings of superiority, often wonders if your interest in them is rather one of remuneration than humanitarian service. Don't contemptuously blame the public and the spirit of the times because of the many and diverse economic phases effecting your welfare, but chide yourselves because you fail to read aright the trend of public thought.

Must the brief for our preservation as individual physicians be one of self-indictment by our own acts, to be subjected to trial and inevitable conviction by jurors not our peers? If so, what a plight for medicine and a pitiful plight for physicians. Awaken! Our quest in life should be not only for honors and sustenance, but also the search to eradicate the causes jeopardizing the future of medicine and your welfare, and the determination to safeguard the future to those who will surely follow you. Don't remain passive to these realities, while politics, economics, and art are indulging in an orgy.

Man is not born whom God did not endow with gifts or talents to develop and use wisely. Concerning the profession as a whole it is regrettable that some recognize the power of speech only when danger threatens them by agencies from without, and then likely, some secretly hoped for some invention to do their thinking. Today, we find men who through sheer fear of losing their freedom to pursue their vocation unshackled become panic-stricken. Yet only yesterday they basked in only the reflection of their diploma and license—serene, unafraid of molestation by outside agencies, believing they were safely protected by the combined forces, and concerted action of the able representatives of our nation-wide

Economics

Evaluation of the Ideals and Ethics of the Present Day Physician

GEORGE W UNSWORTH, M D , *Suffern*
President, Rockland County Medical Society

The Oath is the foundation of the physician's religion. The ideals and the Rules of Ethics of our profession are concentrated in the concise code known as the Hippocratic Oath. The various medical creeds that have come down through the years simply reflect different interpretations of the Oath. Today we find they have been scrambled together and given the name of Medical Ethics.

Ideals mean the highest standard of excellence—always approachable if not attainable, ethics treats of the principles of right conduct in our relations with society and is applicable as our guide governing our mutual relations as physicians.

The prime objective of medicine is the service it can render to humanity. The ethical ideal is the concrete expression of our responsibilities, sacred in the sense we are permitted to exercise our limited power over life and death. Our oath of allegiance to these principles is the dedication of our lives—our knowledge, our talents, and our physical being—to service for suffering humanity. Nothing else. Though the noblest vocation in life, yet the real drama of medicine, full of surprises, sacrifices, triumphs, and failures, the tragedies and comedies, has not been portrayed or told.

The Principles of Medical Ethics, adopted after modification by the American Medical Association were taken from the Percival Code, compiled by Dr Percival over one hundred years ago, who used the basic principle of the Hippocratic Oath. It is significant that the survival and development of these first principles is the final test and measure of the value which society, as a whole, throughout these many years, has put on these ethical principles.

Despite the evolution of our present Principles of Medical Ethics, with its re-

visions, additions, and changes of wording, essential to enable the physician to cope with the many and diverse economic problems ever confronting the profession, the basic principle still remains, that is, the physician's responsibility in service to humanity, and reward or financial gain a subordinate consideration. Read them thoughtfully and you will be amply rewarded in practicing its precepts.

Some of us forget that the "norm" or "ultimate good" on which medical ethics is based is primarily the resolve to maintain such standards and safeguards necessary for the best medical care and the protection of all members of the community. If this fundamental tenet is understood by both physicians and society, then traditional medicine, regarded as a science and practiced as an art, will survive the surging onslaughts of criticism by those who seek to destroy its individualism.

Our forebears in medicine had foresight when they adopted a code of medical ethics and the wisdom to revise them suitable to their time. They visualized the future of medicine, one far advanced beyond the best medical thought of their day. They thought of a more learned and cultured society ministered to by more enlightened and better trained physicians, yet they failed to foresee the importance of how economics would affect the future practice of medicine. Yet overshadowing their knowledge and experiences as physicians was that deep interest in future medicine and the practitioner. They knew that when "conquest of disease" was placed subordinate to reward or fee (and there were greedy and unscrupulous physicians then as there are now—worshippers of gold, and lacking in compassion for the misery and illness of man), that when physicians condescended

Read before the Rockland County Medical Society, Spring Valley, February 24, 1937

Medical News

Albany County

THE PROBLEM of anginal heart failure was the topic of the Medical Society of the County of Albany at its meeting on May 19. The chief speaker was Dr H M Marvin, associate clinical professor of medicine at Yale. Discussion was led by Dr James F Rooney.

Bronx County

THE PROGRAM of the Bronx County Medical Society on May 19 included addresses on Legislative Activities of the State Medical Society by H L Nelms, M D, Chairman, Committee on Legislation, New York State Medical Society and Joseph Lawrence, M D, Executive Officer New York State Medical Society, and on "Dental Care of Children—Its Effect on Later Health" by Louis Wack, DDS. Discussion opened by S B Gerstner, DDS.

Cortland County

DR. STUART B BLAKELY of Binghamton, spoke on May 21 at the meeting of the Cortland County Medical Society in the Cortland Free Library building, on "Some of the Common Gynecological Conditions—Their Diagnosis and Treatment." His address was illustrated.

Chemung County

A SERIES of post-graduate medical lectures on syphilis was given on Thursdays during April and the first Thursday in May at noon at Hotel Wagner, Bath and at 8 30 in the evening in Elmira. The lectures were arranged for the Chemung and Steuben County Medical Societies under the sponsorship of the Committee on Public Health and Medical Education of the New York State Medical Society.

Chenango County

DR. W LEE DODGE of Afton died at his home on April 3, aged 64. He was a well known physician and last year served as president of the Chenango County Medical Society of which he had been a member for many years.

Dutchess County

THE DUTCHESS COUNTY MEDICAL SOCIETY met on April 14 in Poughkeepsie. The speaker was Dr Herbert Mohan, chief neurological clinic, St. Vincent's hospital, New York city. His topic "Neurology from the general practitioner's viewpoint"

DRS MATHER CLEVELAND AND DAVID BOSWORTH of New York city read papers on "A Critical Analysis of 50 Consecutive Cases of Fracture of the Neck of the Femur, Emphasizing Certain Causes of Non-union" at a meeting of the Dutchess County Medical society on May 12 at the Amrita club, Poughkeepsie.

Erie County

THE WOMEN PHYSICIANS' league of Western New York honored the four women who graduate this June from the University of Buffalo Medical College at a dinner in the Town club in Buffalo on May 21.

This group of four includes Mrs Edwin J Lenahan, Mrs R Leshe Murray and the Misses Ellen Nicholson and Alice Challen.

An unusual feature of this graduating class is the presence of two married women, both of them with children, who have succeeded in carrying on their arduous studies while keeping on with their home making. Mrs Lenahan, who is a D'Youville college graduate, has four children and Mrs Murray, with two children, is a Buffalo Seminary and Vassar college graduate. Mrs Murray is following in the footsteps of a notable family, her father having been the late Dr Arthur G Bennett, noted eye specialist, her brother, Dr Arthur L Bennett and her mother, Mrs Alice Ross Bennett, both having doctorates.

Dr Louise Beamis-Hood was chairman of the dinner, with Dr March and Dr Margaret Warwick Schley assisting.

PHYSICIANS OF ERIE COUNTY, who bore a major burden of depression relief costs through free services to the indigent, ask that when the ERB is transferred to the County Department of Social Welfare in July, a reasonable plan of medical care and payment be adopted.

Their demand is embodied in a resolution unanimously adopted at a meeting of the

medical societies Little did they know that not science, not art, but emotions rule the world

Colleagues, the responsibility for the future of medicine rests entirely upon you! The true physician is honest and sincere, with a sense of true values in people, and a friendly courteous attitude towards every one. This is the heritage handed down to him by those pioneers who invaded virgin fields in the cause of medicine

Sometimes I wonder whether the majority of physicians really give thought to medical ethics Do they know that life can offer no greater gift than friendship, and that real friendship is founded on courtesy, kindness, and understanding One of the aims of our Society should be to foster friendship, to bring us into closer harmony and understanding Courtesy is worth cultivating It means a kindly considerate attitude toward every one It is an expression of good fellowship—a symbol of fine breeding It springs naturally from the kindly heart. Culture, too, unmistakably has its place in ethical relations There is nothing wrong with medicine, but with us Our harvest depends upon the quality of the soil and the kind of seed we sow Society justly complains that many physicians concern themselves more with what they think of them than giving expression of their own true selves Another accusation is that

some physicians are not immune from wearing the mask of pretense—the pretense of impressing others—their patients and their friends, and sometimes their colleagues—as to their abilities, often to deceive, and which sooner or later no amount of cleverness can conceal

We should not be satisfied to be right, unless we can prove others to be wrong Our medical knowledge may give weight, but accomplishments give luster, and many more patients see than weigh

Faith is the great lever of life. Without it man can do nothing, with it all things are possible Do we, as physicians, have that abiding faith in the integrity of each other?

Our ethics, the guiding symbols of the physician's life, is like some rich mosaic made up of many beautiful pieces Its glow is the reflection of friendship Its pattern is woven in our associations of unity, peace, and good-will

Always remember it is the things we do rather than the things done to us, it is your thoughts, your kindness, your interest in one another, your loyalty, your sincerity and your unbounded faith, your smile, and the grip of comradeship All of these united give strength to the bonds of fellowship—inseparable, always an imperishable monument to us, the living, and the dead

OLDEST MEDICAL SOCIETIES

New England is aroused when any other section claims to be more ancient or, shall we say, more antique A newspaper remark that the Westchester County Medical Society was the oldest county society in the United States, at its recent celebration of its 140th anniversary, prompts Dr Creighton Barker, Administrative Secretary of the Connecticut State Medical Society, to write to the New York *Herald Tribune* that this is "quite inaccurate." Not counting the Massachusetts Medical Society, founded in 1781, as it was not a county unit, he reminds us that the New Haven County Association was founded in 1784 Furthermore

There are eight county medical associations in the State of Connecticut, and each of them was founded before 1797, the date of the establishment of the Westchester

County association, and in 1792 they consolidated in the formation of the Connecticut State Medical Society, which was chartered by the General Assembly of the state in that year On July 23, 1766, fourteen gentlemen of New Jersey met in the town of New Brunswick and formed the Medical Society of New Jersey, this society antedates all others, but its activities were suspended from 1795 to 1807

HOW HE CAME DOWN

"Hullo, haven't seen you for some time."
 "Been in bed seven weeks"
 "Oh, that's too bad! 'Flu, I suppose?"
 "Yes—and crashed!"

—*Colorado Medicines*

gram included a discussion of pre-natal and post-natal care by Dr Raymond J Pieri of Syracuse. A conference on tumor was held at the House of the Good Samaritan at 5 30

DR S E SIMPSON, county sanatorium superintendent, was named director of the Jefferson county tuberculosis and public health association to fill the unexpired term of Mrs George Diefendorf, removed to Syracuse, at the regular meeting of the directors held at the Black River Valley Club on May 18

Kings County

THE PROGRAM of the Medical Society of the County of Kings on May 18 was on the subject "Lymphopathia Venerea" (a) General Considerations and Proctological Aspects—Collier F Martin, M D, F A C S, Philadelphia, Pa (b) Surgical Difficulties—Walter Estell Lee, M D, F A C S, Philadelphia, Pa, and Robert R Impink, M D, Philadelphia, Pa

CONTINUING TO COMBAT the fraudulent health talks and medical advertisements broadcast by radio to a gullible public, the Medical Society of the County of Kings offers four programs over Station WBBC during the month of June.

The society's publication for May directs an attack at "fake advertising" and speaking of its own programs, reports that "ours is to be a program of health promotion and disease prevention

"We realized that we had a tremendous problem on our hands, we also realized that we would not be able to convince or convert all of our listeners. We did know, however, being fairly good judges of human nature, that we would reach a good many people who were sincerely interested in a supervised medical broadcasting program which would be given by organized medicine," the article says

On June 7, "Care of the Hair and Skin" was discussed, on June 14, "Falling Hair," on June 21, "Pimples" and on June 28, "Moles and Blemishes"

DR TSUNE-CHI YU, Chinese Consul General in New York, was the chief speaker at the second annual luncheon of the Women's Auxiliary of the Kings County Medical Society in the Hotel Astor, Manhattan, on May 11

Speaking on "The Women of China," Dr Yu told the 650 guests that Chinese women had aided greatly in the advancement of peace and democracy in their native country

Among the prominent Brooklynites who

addressed the gathering were Mrs John L Bauer, president of the Women's Auxiliary of the New York State Medical Society, Dr Charles H. Goodrich, president-elect of the New York State Medical Society, and Dr Thomas A McGoldrick, president of the Kings County Medical Society. Another speaker was Mrs Augustus Keth of Altoona, Pa, president-elect of the Women's Auxiliary of the American Medical Association. She said in part "Doctors' wives are the unwept, unhonored and unsung heroines of the modern world—and they're bears for punishment

"There are 154,000 doctors in this country, and 72 per cent of them are married. Among that 72 per cent there are just 906 divorced—less than eight-tenths of 1 per cent. These figures show how well the doctor's wife is doing her job

"It's the hardest job of any wife today, for the doctor is the only man not master in his own house. He is at the beck and call of the world, and his wife must stand between him and the world if a tired man is to have any rest

"Being a doctor's wife is one of the hardest feats for a woman—but one of the finest and most rewarding for any woman who wants to leave the world better than she found it"

THE RIDGEBORO MEDICAL SOCIETY held its monthly meeting on May 20, at the Kings County Lighting Company, 67th St. and 4th Ave. Drs Condre, Kaiser and Windorf discussed three unusual cases of interest to the medical profession. Dr Kingsley Roberts of Manhattan discussed "Consumer Co-operative Control in respect to voluntary health associations"

THE REGULAR MEETING of the Bay Ridge Medical Society was held on May 11 at the Shore Road Academy. The scientific session was devoted to a paper by Dr James J. Stefano, of the Brooklyn Hospital on "Analysis and Treatment of Gastro-intestinal Hemorrhage with the Levine Tube." The annual dinner of the Society was held on June 8, at Lundy's Restaurant at Sheepshead Bay

THE ADVANCES which medical science has made in the handling of heretofore incurable cases were stressed in the clinical meeting of the Williamsburg Medical Society on May 10, in the Jewish Sanitarium and Hospital for Chronic Diseases, E 49th St, and Rutland Road. Among the doctors presenting papers were Meyer Ginsberg, Henry Joachim, Benjamin Koven, Bernard S Epstein, Milton G Wasch, Alexander Lew-

Erie County Medical Society in Hotel Statler, on May 17

Under the system that has prevailed, it was pointed out by the doctors, some of them gave much time to treating the poor without pay, while a few garnered more than a just share of payment from Federal, state, and county relief funds

The physicians estimate that since 1932 they have donated \$1,000,000 worth of medical service to the county's indigent, exclusive of City Hospital

Henceforth, they urge in the resolution adopted, indigent patients should be given full free choice of whom they shall call in when sick. Co-operation with the City Department of Social Welfare is provided for by the resolution, as well as an agreement among individual physicians to abide by regulations of the society's executive committee.

The resolution, introduced by Dr Joseph C O'Gorman, directs that an official representative of the society confer with Mayor Zimmermann to work out the new program

Another provision is that indigents shall be provided with a list of doctors in the ward in which they live, so they can choose.

Dealing with another matter, the society voted against asking the state for some \$7500 to finance continuation of a maternity mortality survey

Dr James L Gallagher argued that acceptance of the money would be "obligating this society to the State Department of Health and furnishing the entering wedge for state medicine to gain control"

AN "OBSTETRICS COUNCIL" will be organized by the Medical Society of the County of Erie to carry on educational and other activities designed to bring down Buffalo's maternal mortality rate.

Formation of the council was decided upon at the society's April meeting in Hotel Statler after Dr Marvin Israel, chairman of a special committee appointed on April 16, 1934, to make a local survey of maternal mortality, had recommended the move.

Under the plan each hospital in the city will be requested to appoint one of its obstetricians, who must be a member of the society, to serve on the proposed council

The group will then organize and elect its officers. The council's functions will be to carry forward the work begun by the Maternal Mortality Survey Committee, to promote public education along lines calculated to reduce maternal mortality, to act as a source of authoritative information on obstetrics, and to work to improve hospitalization and introduce and maintain

standard approved obstetrical techniques in all the institutions of the city

ABSENCE OF A PHYSICIAN on the citizens' advisory committee recently named by Mayor Zimmermann to survey the local relief situation was deplored by Dr Herbert R. Bauckus, past president of the Medical Society of the County of Erie, at a health officers' meeting in Buffalo on April 28

He declared the medical profession, sympathetic to and fully cognizant of the health and medical needs of the suffering and unfortunate through constant professional contact, should be represented on any such committee

Dr Bauckus was one of a long list of speakers at the State Health department's health education institute for Western New York health officers, conducted in the State building and attended by doctors from seven counties

Health officers, who should be the leaders in health education work, have neglected this phase of their duty, according to Dr Archibald S Dean, district state health director, who presided at the meeting

Burt R. Richards of Albany, State Health department director of public health education declared "If we had done more to bring health facts before the public the quacks would not have had such an easy time"

Fulton County

MEMBERS of the Fulton County Medical Society were guests of Dr B E Chapman at his Summer home on the Sacandaga reservoir on May 19 at the annual Spring outing of the society

DR J EDWARD GRANT was re-elected president of the Fulton County Tuberculosis and Public Health Society at the annual meeting. He has held the office a large part of the time the society has been in existence during the past eighteen years

Herkimer County

A SERIES of POSTGRADUATE LECTURES on the complications of pregnancy were given at the North School in Herkimer in May. The committee in charge of the program were Dr James F Gallo, Dr G A Burgin and Dr G J Frank

Jefferson County

THE REGULAR MEETING of the Jefferson County Medical society was held on May 6 in the Black River Valley club. The pro-

Nassau County

THE THIRD ANNUAL JOINT DINNER meeting and sports day of the Nassau and Westchester County Medical Societies was held Wednesday, June 2nd, at the North Country Club in Port Washington, Long Island. The program for the afternoon included team contests and individual play in golf, tennis, playground baseball with a ten-man team and horseshoe pitching. After dinner the Nassau and Westchester men vied with each other in a program of amusing entertainment, furnished by members of both groups, on the lines of an amateur hour program, singing, story-telling, yodeling, dancing, sleight of hand, and other types of entertainment.

New York County

DR. NATHANIEL ROSS, assistant clinical professor of psychiatry at the New York University College of Medicine, has been named physician in charge of the Committee for the Study of Suicide, an organization formed for the study of self-inflicted deaths which occur in the Manhattan area.

A comprehensive one-year survey of Manhattan's suicides is planned by the group, according to Dr John Wyckoff, dean of the College of Medicine, who selected Dr Ross as the head of the new organization.

Prof Karl M Bowman, director of the psychiatric division of Bellevue Hospital, Dr Gregory Zilboorg, director of research of the committee, and Dean Wyckoff, with about 50 psychiatrists and social workers, will participate in the project.

Oswego County

WITH ELECTION OF Willard J Hall as president of Oswego hospital, at a meeting of the Board of Trustees on April 19, steps were taken which, it is hoped by hospital trustees, will result in a speedy settlement of difficulties between the Department of Welfare, the Oswego Academy of Medicine, and the hospital authorities.

For more than a year, there have been differences between the city of Oswego and the hospital, although the latter was not in position to act conclusively, because of resignation of its medical and surgical staff.

Members of the medical and surgical staff of the hospital last year presented a demand to the city they be paid for treating and caring for city welfare cases in the hospital the total cost to be about \$16,000 a year. The staff proposed this sum would be divided equally among all staff members,

or, in effect, that each staff member, regardless of the work performed, would receive a fixed annual sum for services to the city. City Attorney Harry C Mizen ruled this was incompatible with decisions by the state comptroller, and that the city could not pay a lump sum for services, but could pay on accounts regularly rendered.

Resignation of the staff followed, and left the hospital virtually helpless to proceed. The city then started a plan of retaining, at regular fees, such physicians and surgeons as were needed for relief cases, and this has cut hospital revenues, and city costs.

A committee of physicians, representing the Academy, has been negotiating with city authorities recently, and it is expected an amicable arrangement will be reached which will be fair to all parties. It may be based on an increased sum per diem to be paid to the hospital per patient, with the hospital to reimburse the physicians for their work, which is the only basis, the city attorney rules, on which the city can make payments. The hospital receives \$4 per patient day now, and under the new plan this will be advanced to \$6.50 or about that sum.

Rensselaer County

DR. STANTON P HULL of Troy has purchased the three-story and basement building at 507 Broadway, adjoining his present property for the establishment of an institution of physiotherapy and fever therapy. Dr Hull will be assisted by Dr Vincent Laquidera.

Richmond County

AN APPEAL TO PHYSICIANS to help control scarlet fever on Staten Island has been issued by Dr William C Buntin, president of the Richmond County Medical Society. He also is Richmond Borough superintendent of the Health Department.

In his announcement Dr Buntin said, "Since January 1, there have been over 300 cases and, fortunately, only one death. Of these, too high a percentage have been secondary cases, some of which might have been avoided if the case of origin had been more promptly reported so adequate quarantine could have been established."

Suffolk County

A CARD PARTY was held by the Woman's Auxiliary to the Suffolk County Medical Society at Bay Shore on May 4, the proceeds to go toward the new equipment for the Boy Scouts' Infirmary at Camp Baiting Hollow.

tan, Abraham Walzer, William J. Zack, A. M. Rabiner, and Morton Hand

MEMBERS of the South Brooklyn Medical Society, at its meeting on May 13, listened to papers on "Psycho-analysis in General Practice Hypnosis explained and demonstrated" by Sándor Lorand, M.D., Psychiat, Mt. Sinai Hospital. Discussion Carroll Leja Nichols, M.D., Cons. Neur. Bushwick Hospital, and "Insulin improved by non-protein amines. A chemical discussion" by Raymond A. Warburton, M.D.

Madison County

THE ANNUAL COURSE OF LECTURES of the Madison County Medical Society are being presented at the Hotel Oneida. The program: May 12, The Treatment of Edema, Dr. Nelson G. Russell, Buffalo; May 19, Dyspnea and Its Treatment, Dr. E. H. Heath, Buffalo; June 2, Measures for the Relief of Distress Following Meals, Dr. A. H. Aaron, Buffalo; June 9, Results of Modern Methods in Treatment of Anemia, Dr. F. D. Leopold, Buffalo; June 16, How Shall We Treat Irregular Hearts? Dr. C. W. Greene, Buffalo; June 23, Diagnosis and Treatment of Unconscious States, Dr. E. A. Sharp, Buffalo.

MEMBERS of the auxiliary of the Madison County Medical Society heard a talk on "Cancer" at its regular dinner meeting on May 13, at Hotel Oneida. Dr. Lee S. Preston was the speaker. Mrs. Robert L. Crockett presided.

Plans for the June meeting were discussed and the next session of the auxiliary will be held the third Thursday in June instead of on the second as usual. It is possible the auxiliary will hold a joint outing with the County Medical Society.

Monroe County

THE ANNUAL MEETING of the Rochester Academy of Medicine took place on May 6, at the clubhouse, Prince Street. Following the business meeting, members were addressed by Prof. Henry F. Helmholtz of the University of Minnesota, president of the American Pediatric Society and former editor of the American Journal of Diseases of Children. He is a director of a section of Mayo Clinic. During his stay in Rochester, he was the guest of Dr. George H. Whipple of the University of Rochester Medical School. A dinner was given in his honor at the University Club by Dr. A. D. Kaiser, vice-president of the academy.

Montgomery County

DR. FRANCIS R. IRVING, of Syracuse, addressed the Medical Society of the County of Montgomery at the Elks Club in Amsterdam on May 13, on "The Hemorrhagic States of Pregnancy."

FOR LONG LIFE EAT LITTLE! That is the counsel of Dr. Henry C. Young, health officer of Hagaman, Montgomery County, who received a memorial scroll from Dr. Edward S. Godfrey Jr., State Commissioner of Health, in commemoration of 50 years of service, on May 3.

"More people die of overeating than starvation," the veteran physician declared, urging a "simple, wholesome diet, such as my own."

Dr. Young's breakfast, at 10 a. m., comprises the juice of a single orange and a half-cup of coffee. At noon he has a small cup of broth or soup, buttered crackers and another half cup of coffee. Dinner, at 6 p. m., includes a small portion of meat, two vegetables and weak tea.

"The best meal of the day for me is between midnight and 1 a. m.," he continued. "Then I have a cup of stale bread or crackers, in milk. Now there are many good arguments in favor of midnight lunches—light lunches, of course."

"In the final analysis we are all grown-up babies. Did you ever hear of a baby going to sleep on an empty stomach? No, of course you didn't. Babies are always fed before they go to sleep. By the same token, a little food taken before one goes to bed is conducive to a good night's rest."

Discussing the habit of smoking, Dr. Young said, "personally, I smoke only once a day—from the time I get up until the time I go to bed." He smokes both pipe and cigars, but admitted a preference for a 40-year-old meerschaum, battered somewhat from being emptied by tapping the rim on various surfaces.

"The curse of smoking is inhaling," he said. "If anyone wants to kill himself, slowly but surely, let him inhale while he smokes." As for women smoking, "it kind of hurts me to see them do it," he commented. "It might be a little bit of a moral thing with me, but I feel that women would be better off if they didn't smoke."

In presenting the memorial scroll to the veteran health officer, Dr. Godfrey addressed him as "young Dr. Young," and explained the parchment was "a slight token of our esteem for 50 years of faithful and continuous service." Last year Dr. Young was reappointed village health officer for another four-year term.

ing their files and buildings to the inspection of investigators. But the proprietary hospitals, institutions operated on a profit-earning basis, were less willing to cooperate. Of those approached, two refused to make appointments for the interview and in three no information of importance was obtained.

Too often the obstetrical nursing in the proprietary hospitals is done by undergraduate "practical" nurses. Each physician in

these hospitals makes his own policies and many of the hospitals are poorly equipped for maternity care. In one institution, the delivery room, which in well-run hospitals should be in a separate wing from the other departments of the institution to prevent infection, was part of the general operating room suite with only a utility room separating them. As yet, satisfactory control of these proprietary hospitals has not been established, according to the Association.

A Hospital Training School for Executives

THE HOSPITAL FOR JOINT DISEASES, in New York City, is making an interesting experiment in training graduates in medicine to become hospital executives. It was only after five years of careful consideration that the hospital authorities decided to create the position of "Resident in Hospital Administration," and the results have been so good that the program of training that was tried out has been definitely adopted.

Not everyone realizes the complexity and diversification of the task of directing a hospital. It touches in one way and another pretty much of the whole field of man's social and economic life. As Dr. J. J. Golub, Director of the Hospital for Joint Diseases, says in the *Journal of the AMA*, the hospital must interest itself not only in the patient's disease and its treatment, but in his social and economic influences, his home environment and background, his fate after discharge, and the situation of his family during and after his illness. In fact, he declares:

"Under the influence of this expanding concept of hospital aims, the work of hospital administration goes more and more beyond its walls. It now involves the articulation of the hospital with the community, government, central chests, federations, foundations and welfare agencies, and with the medical, dental and nursing professions. It is concerned with and affected by the problems facing the medical and nursing professions. Such questions as costs of medical care, economic burdens of the physician, hospital and out-patient department abuses, open or closed hospital policy, health insurance, periodic health examinations, socialization of medicine, legislation affecting medicine, specialization and the family physician, ethics, cults and the standards of medical education, all of which seriously engage the interest of the medical profession, are of vital interest to the hospital. Such questions

as nursing education, supply, demand and distribution of nurses, grading of nurses' schools, group nursing, nurses' and students' hours of work, nursing standards and duties, and nurses' earnings, which are of primary interest to the nursing profession, also deeply concern the hospital.

"A hospital executive must know all these fields."

So the requirements for candidates were set high. They include:

- 1 Graduation from a grade A medical school.
- 2 Two years general internship in a hospital with a bed capacity of at least 200.
- 3 Reliable testimony and observation as to personal qualities, such as aptitude for administration, character, capacity to learn, resourcefulness, vision, social mindedness, ability to work hard and well with others, and poise.
- 4 A desire to make hospital administration a life work rather than a means of finding temporary employment.

The course of study is laid out under a Three-Year Plan, as follows:

First Year

Junior Resident in Hospital Administration
Study and Supervision of Dept. Group A

- 1 Admitting department
- 2 House staff
- 3 Emergency and ambulance service
- 4 Deaths and autopsies
- 5 Record department and library
- 6 Surgical operating rooms, maternity delivery rooms and anesthesia service
- 7 Nursing service
- 8 Social service department

Second Year

Intermediate Resident in Hosp. Administration
Study and Supervision of Dept. Group B

- 9 Laboratories
- 10 X-ray service
- 11 Pharmacy
12. Other professional services

Hospital News

Serious Flaws Revealed in Maternity Care

LACK OF RESIDENT DOCTORS and nurses trained for the special care of mothers in childbirth is an outstanding weakness of governmental, voluntary and proprietary hospitals in the Metropolitan area, according to the Maternity Center Association in its study of obstetric facilities made for the Hospital Survey for New York, under the sponsorship of the United Hospital Fund.

In only half of the municipal hospitals visited in New York City has the resident physician had specialist training for the care of mothers in childbirth, the findings show. In the voluntary hospitals visited, three-fourths have no resident physician with previous special training in obstetrics. Of the hospitals with schools of nursing, two-thirds of the nurses in charge of student teaching of obstetrics have no special training in the subject.

In contrast to this lack of trained staff, the number of hospital beds for maternity patients in New York City is found to be sufficient. By 1940, it is estimated that there will be enough beds to care for 104,220 births or 7 per cent more than the total number of estimated births in that year, assuming that the birth rate will be 12 per thousand in a population of 8,109,000.

The Association found that 81 per cent of the total births in New York City, 70 per cent of the births in the five New Jersey counties included in the Metropolitan area, 78.8 per cent in Westchester County and 57.9 per cent in Nassau County occur in hospitals.

In virtually all hospitals offering maternity services, the nurseries have special consideration. Even in those institutions where patients' beds are crowded and wards disorderly, the nursery is roomy and apparently well-cared-for.

"Thirty of the thirty-four hospitals visited conduct prenatal out-patient services. In the majority of them, the space and equipment are not adequate for the number of patients registered. A few of the hospitals provide individual rooms or cubicles for the examination of patients. The majority of these dispensaries have curtains between

the tables, but in some the curtains are never drawn."

In only a few of the prenatal clinics is suitable provision made for the patient to undress for examination in privacy. Because of lack of facilities, patients are forced to wait long hours to be examined, the examination is hurried and the patients frequently feel poorly repaid for the effort they made to get to the clinic.

"While individual prenatal records are fairly complete," the Association found, "few hospitals could readily supply information about the volume of service or the month of pregnancy in which patients are registering and few prenatal clinics could tell how many of their registered patients were delivered in hospitals. On the whole, opportunities for the patients to secure the kind of care they need are few."

In addition to the clinics conducted by the municipal and voluntary hospitals, there are a number of unattached clinics conducted by the Department of Health and several unofficial agencies in New York. At the present time many of the patients attending these unattached prenatal dispensaries have no definite plan for delivery care, and often patients are sent at the last moment to a hospital which has no record of their prenatal condition or care. There is no plan which makes the records of patients who attend these dispensaries available to the physicians who deliver them and obviously there is no continuity in the care these patients receive.

"The number of patients delivered in their homes has rapidly fallen since 1930 and many of the services for the care of mothers in their homes have been discontinued or are being reduced in scope. In one section of New York, where a large home service has been discontinued, the one hospital in the district is unable to meet the needs of that district so that patients living there are forced to seek care in hospitals a considerable distance from home, which makes prenatal care difficult to obtain."

The governmental and voluntary hospitals as a whole cooperated in the Survey, open-

6th Ave., named for a famous Brooklyn surgeon. The proposed change does not affect this institution

A campaign is to be started for a fund to build a modern hospital on or near the site of the present Samaritan, to be constructed on the unit plan. Pending this work, no more bed patients will be accepted and cases at hand will be gradually eliminated. Day clinics will continue

ST JOHN'S HOSPITAL, Long Island City, has launched a drive for funds for new equipment.

ILION HOSPITAL is planning a new addition.

THE GLENRIDGE SANATORIUM at Schenectady contemplates building new living quarters for the superintendent and staff, to cost around \$200,000

THE ENLARGED AND MODERNIZED Bath Hospital opened on May 12. The improvements cost \$130,000

THE SIX-DAY DRIVE on May 10-15 to raise \$500,000 to build the new Glens Falls Hospital was so successful that it ran \$1,412 over the mark

GROUND HAS BEEN BROKEN for the new Good Samaritan Hospital at Suffern. It will be completed early next spring

EXPANSION of the State Institute for the Study of Malignant Diseases, better known as the Gratwick Laboratory, in Buffalo, is contemplated. Prospective plans provide not only for increasing the bed capacity from 32 to 100 patients, but also for the installation of one of the most powerful X-ray machines in the country, which is expected to be beneficial to the 7,000 patients who come for aid annually

THE SISTERS of the Poor of St. Francis, who maintain a retreat at Warwick, are contemplating the construction of a new hospital. A site has been acquired and it is expected that the new hospital will be opened in 1938

Newsy Notes

THE SECOND ANNIVERSARY of the Associated Hospital Service of New York, celebrated on May 7 at the Metropolitan Club, Fifth Avenue and Sixtieth Street, marked the attainment of an enrollment of more than 355,000, it was announced by Frank Van Dyk, executive director. Mr. Van Dyk said that in reaching this number in two years the service, a non-profit corporation which administers a plan of group hospitalization for earners of wages at 3 cents a day, had set a new world's record.

The London Hospital Savings Association, which now has an enrollment of 1,750,000 and is the largest in the world, had only 160,000 contributors at the end of its second year, he said.

The anniversary was also the occasion of taking over a second floor in the office building at 370 Lexington Avenue, for the 200 employees of the service, a number which is in sharp contrast to the staff of eight with which the service opened on May 7, 1935.

THE HOSPITAL SERVICE CORPORATION of Jefferson County was organized at Watertown on May 7, with Harvey R. Waite, president of the Agricultural Insurance Company, as president.

"THE LITTLE RED WAGON," a store on wheels, containing candy, cigarettes, stationery and newspapers, started on May 17, on its journey through the corridors of the Deaconess hospital, in Buffalo.

According to plans of the Women's board two members will volunteer each day to trundle the "Wagon" through the corridors right to the bedside of every patient. When the venture becomes self-supporting, the board will engage a permanent vendor.

THE PEEKSKILL HOSPITAL Babies Alumni Organization has been formed, with the approval of the Board of Directors of the Peekskill Hospital. The Alumni are being

- 13 Outpatient department
- 14 Dietary service
- 15 Housekeeping and laundry
- 16 Engineering and maintenance of plant

Third Year

Senior Resident in Hospital Administration
Study and Supervision of Departmental
Group C

- 17 Personnel administration
- 18 Accounting and finance
- 19 Purchase and issue
- 20 Medical staff organization
- 21 Board of trustees
- 22 Community relationship
- 23 Planning and construction
- 24 A thesis

The Resident receives \$50 a month during the first year, \$75 in the second, and \$100 in the third, with complete maintenance. Dr. Golub suggests

"In a large community where there is a university, several hospitals introducing thus or a similar plan of training may affiliate with the university for a course of supplementary lectures on the subject matters discussed here, leading to a degree of Doctor in Hospital Administration.

"When opportunities in residencies in hospital administration become generally known and widespread, they cannot fail to attract properly qualified persons. With this, the problem will arise of finding suitable places for them. It is not likely that even the most able would be ready to assume the responsibilities of executive work as heads of large hospitals, but they would be prepared to head small hospitals, or to become assistants to executive heads of large hospitals, or heads of dispensaries or diagnostic clinics, and to be advanced on their records to greater responsibilities and higher positions."

Improvements

PLANS HAVE BEEN FILED for the construction of a six-story hospital at 415 West Fifty-first street, New York City, by St. Clare's Hospital, Reverend Mother M. Alice, superior and president. Robert J. Reiley, architect, places the cost at \$255,000.

. . .

PRELIMINARY PLANS for a hospital building of twelve stories, and a penthouse, designed to be one of the world centers of cancer research and treatment, have been filed for the block bounded by East Sixty-seventh and Sixty-eighth Streets, York and First Avenues, New York City.

This will be the new home of the Memorial Hospital for the Treatment of Cancer and Allied Diseases, now occupying the Central Park West blockfront between 105th and 106th Street. Dr. James Ewing is director.

James Gamble Rogers, the architect, estimated the cost of the new hospital at \$2,800,000 in the tentative plans he presented to the Manhattan Department of Buildings, but officials of the hospital explained that the final cost and the final layout had not yet been determined.

Excavation work probably will start on the site within a few weeks. The construction of the buildings probably will require about twenty months. The site for the new building was presented to the Memorial

Hospital by John D. Rockefeller Jr. about a year ago. The General Education Board made funds available for the building.

A \$250,000 SUBSCRIPTION by the Commonwealth Fund of New York to enlarge the facilities of the Columbia School of Medicine has been announced by Dr. Nicholas Murray Butler, president of the university. The subscription covers almost one-half the cost of the \$600,000 building project.

TARRYTOWN HOSPITAL AUTHORITIES are campaigning to raise \$27,000, part to be used for general improvements.

A SIX-STORY HOSPITAL and dormitory, to cost \$750,000, is to be built at 43 St. Mark's Place, by the Warschauer Haym Salomon Home for the Aged.

SAMARITAN HOSPITAL, in Brooklyn, is again to be torn down and rebuilt. It stands at 4th Ave. and 17th St., in a building that was erected when the service demands of its predecessor structure were found to have outrun its facilities.

The hospital has a branch, known as the Skene Sanitarium, on President St., near

Alumnae of the Manhattan Eye, Ear, Nose and Throat Hospital

AN "ALL STAR VARIETY SHOW" was staged at the Waldorf-Astoria on May 22 for the benefit of Israel Zion Hospital's building fund

The hospital, now the fourth largest Jewish hospital in the country, will be the second largest when the new eight-story addition is completed.

THE BUFFALO STATE HOSPITAL Employees' association held a dinner dance on May 15 in Hotel Lafayette

THE WOMEN'S BOARD of the Leonard Hospital, in Troy, have planned a card party and food sale on the lawn of the hospital, Saturday, June 26, for the general hospital benefit fund

The board is composed of wives of the medical staff doctors, women's hospital auxiliary, general duty nurses and members of the Alumnae Association.

MEMBERS of the 1937 graduating class of the Samaritan Hospital Nurses' Training School, in Troy, were guests at a banquet and dance in observance of the 35th anniversary of the Alumnae Association, at the Hotel Troy on May 13. The "Twigs" No 1 of Samaritan Hospital held a fashion show and card party on May 3 in the living room of the hospital. The proceeds will go to the hospital. This organization of young ladies has for its per-

sonnel a group of students from the Emma Willard School

THE TRUSTEES of the Potts Memorial Hospital, at Livingston, gave a dinner at the General Worth Hotel in Hudson on April 29, to acquaint the people of Hudson more fully with the work being done at the hospital. Dr Harry A Patterson, superintendent, and Dr Charles Hatfield, president of the board, were the speakers. Motion pictures of life and work at the institution were shown. The dinner was the first of a series of occasions through which the work at the Potts Memorial Hospital is to be brought closer to the people of Hudson and Columbia county

THE TENTH ANNUAL BALL for the benefit of the Nyack Hospital was held on May 14 in the auditorium of the Rockland State Hospital at Orangeburg

HONORING HIS 32 YEARS of service as member of the board of trustees of the Hudson City hospital from which he recently resigned after having served as president for 31 years, the trustees of the hospital tendered Judge Samuel B Coffin a dinner on May 12 at the General Worth Hotel in Hudson

THE WOMEN'S GUILD of the Norwegian Hospital, of Brooklyn, entertained at a tea, reception and musicale Saturday afternoon, May 8, at the Sisters' Home, 46th St. and 4th Ave

At the Helm

ISAAC SIEGMASER was elected to his third successive term as president when the Council of Organizations of Beth-El Hospital held its annual meeting in the Terrace De Luxe, Howard Ave. and Eastern Parkway, on Apr 29

AT A MEETING of the physicians of the Village of Herkimer on May 7 an organization was perfected under the name of the Herkimer Memorial Hospital Staff. Officers selected were: Chief, Dr James W Graves, assistant chief, Dr J E Canfield, secretary, Dr H C Murray, treasurer, Dr F H. Moore

president of the board of managers of the Binghamton City Hospital

MR CARL P WRIGHT, JR., Assistant Superintendent of New Haven General Hospital, became Superintendent of the United Hospital in Port Chester on May 15. Mr Wright succeeds Mr Sidney J Barnes who has been Superintendent for the past eight years and who tendered his resignation last January. Mr Wright was, for several years earlier in his career, assistant to Dr Munger at Grasslands. Later he became associated with Dr S S Goldwater now head of the New York City Department of Hospitals and for the last two years Mr Wright has been Assistant Supt. at the New Haven institution.

Z BENNETT PHELPS has been reelected

sponsored by the Junior Auxiliary of the Hospital

Under the organization all babies born at the hospital will be entitled to membership at one dollar per year, which they may continue each year as long as they live

Funds collected by the association will be used to better equip the maternity ward. One of the projects contemplated is the purchase of a respirator for infants in need of artificial respiration at birth

AT A MEETING in Buffalo on May 14 the managing directors of the various group hospital plans in New York State cities formed a permanent organization.

The state body was formed to disseminate important information and to arrange for a standard accounting method to facilitate the compilation of actuarial statistics on hospitalization experience in the entire state. Benefits to the public participating in hospitalization plans are expected to accrue from the program of the organization.

Cities represented at the meeting included New York, Rochester, Buffalo, Albany, Syracuse, Jamestown and Elmira

SUPERINTENDENT ADRIAN S TAYLOR, M D, reports that on April 5th, as a result of

a campaign conducted among its clientele, the Clifton Springs Sanitarium was able to pay \$50,000 on its mortgage, and at the same time was able to sign a new mortgage agreement for the balance with the mortgagee, Mrs Grace Jones Stewart of Buffalo, whereby she voluntarily reduced the capital debt by an additional \$71,250, refinancing the balance at a lower rate of interest over a long period of years. Four new members have been added to the medical staff

SIR HENRY H DALE, Director of the National Institute for Medical Research, London, lectured on May 7 and 10 at the Mt. Sinai Hospital in New York City on "Acetylcholine as a Chemical Transmitter of the Effects of Nerve Impulses"

ACCORDING TO A RECENT RULING of the Executive Committee of the Medical Board of Beth-el Hospital, in Brooklyn, all members of the staff seeking promotion to the rank of Associate or Attending must pass their respective Board in the specialty in which they seek promotion and all members of the Attending Staff must have passed their Boards in their respective specialty by the Fall of 1939

Events

ST JOHN'S LONG ISLAND City Hospital, the second oldest hospital in Queens, held a reception and dance in the Hotel Commodore ballroom, the night of May 7. Proceeds from the dance will go towards the purchase of much needed hospital equipment

A DINNER was given by the medical staff of Greenpoint Hospital in honor of Dr Charles A. Gordon on May 12 in the Towers Hotel

Dr Thurston Scott Welton, president of the medical board of Greenpoint Hospital, was toastmaster. The Rev Paul J Faustman, assistant director Catholic hospitals of Brooklyn, Dr Frank L Babbott, president of Long Island College of Medicine, and Dr Sigismund S Goldwater, commissioner of hospitals, were among the speakers

THE BOARD OF TRUSTEES, medical staff and auxiliaries of Jamaica Hospital gave a dinner dance in honor of Mortimer Gold, chairman of the circus recently conducted for the benefit of the institution, on May 11, in the Pomonok Club, Flushing. "The success of the circus was due largely to Mr Gold's untiring efforts," said Thomas D Austin, toastmaster

LEADERS in the judicial and political world gathered on May 6 at the Hotel Astor in New York City for a testimonial dinner to Isidor S Schweitzer, President of the Jewish Memorial Hospital

A CARD PARTY for the benefit of the Post Graduate Nurses' Endowment Fund was given on May 20 at Schrafft's, 220 West 57th Street, by the Post Graduate Nurses'

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Libel and Slander—Physical Examination

A case decided a short time ago in the highest court of one of the Southern States is of interest since it shows the extent to which the Courts will protect a physician who has made a physical examination of a party to a lawsuit, and has given testimony with regard to his findings.*

One "A" claimed that without cause a certain "G" had kicked him and that he had sustained serious injuries as a result. He brought an action against "G," and against the "W" Baking Company in whose employ "G" was at the time. In his complaint he alleged that the kick had been the cause of various conditions including a hydrocele, a rectal fistula, and impotency.

The attorneys for the defendants in the action for personal injuries made a request that "A" submit to a physical examination, to which "A" consented. Dr "B," a physician of repute, highly esteemed by the members of his profession, who specialized in genito-urinary work made the examination, which was a complete one. Dr "B" embodied his findings in a letter written to the attorneys for the defendants in that action. Upon the trial of the case the doctor testified and his report was read into evidence. The report included the following statement: "I consider the patient's mental state decidedly abnormal for a man of 25, he is mentally undeveloped in my opinion."

"A" thereafter instituted a libel suit against Dr "B" based upon the said language contained in the report. He alleged in the complaint that the statements concerning his mental condition had no connection with the purposes for which the physical examination was made, and that said statements had been made by Dr "B" without just cause or provocation, and that they were false, malicious, and untrue. He charged that Dr "B" knew the statements to be untrue and had made them for the purpose of reflecting upon his credibility and to humiliate him, and to bring him into discredit as a witness in his personal injury action. He sought damages from the doctor in the sum of \$5,000.00.

The doctor defended the charges on the theory that his letter was a privileged communication both in respect to its delivery

to the attorneys and with respect to its introduction into evidence and being read in Court. Dr "B" contended that he had not intended his language to humiliate the plaintiff and to hold him up to ridicule, but that he had made his report in obedience to his conception of his duty. He claimed that everything he had reported was germane to the issues in the personal injury case, and that in so reporting he had acted in good faith, and with reasonable cause to believe his statements were true.

Upon the trial of the libel action there was very little dispute upon the facts. The defendant, Dr "B," testified that his examination of the plaintiff had been both subjective and objective, and that he had found little or no basis for the plaintiff's claim of extensive injuries and that he necessarily had to go into the plaintiff's mental condition to show the basis for the discrepancy between the injuries claimed as resulting from the kick and what he actually found.

The record of the testimony upon the trial of the libel suit showed no dispute or quarrel between the doctor and "A" during the physical examination, and failed to show any circumstance from which ill will, malice or prejudice on the part of Dr "B" could be inferred.

Upon the conclusion of all the testimony, the jury returned a verdict in favor of the doctor and judgment of dismissal was entered. The plaintiff appealed therefrom to the highest Court in the State, and the verdict was affirmed. In so ruling the Court said in its opinion:

"Privileged communications are either absolutely privileged or qualifiedly privileged. Qualified privilege exists in a larger number of cases than does absolute privilege."

"A communication made in good faith upon any subject matter in which the party has an interest, or in reference to which he has a duty, either legal, moral or social, if made to a person having a corresponding interest or duty is qualifiedly privileged."

"Within this rule defendant had a qualified privilege to make the statement of which plaintiff complains. He had an interest in the subject matter about which he was writing. He had been employed to ascertain plaintiff's physical condition and to communicate the result of his findings to his employers. He had become possessed of information affecting

* Oakes v. Walther, 154 So. 26

their rights and it was clearly his duty to give them that information. From which it follows, that in making his report to his employers defendant committed no actionable wrong, unless he acted maliciously, which the record shows was not the case.

"Plaintiff also charged that the alleged libel was published when defendant testified in plaintiff's suit against the baking company and its co-defendant. It appears that on the trial of that case, defendant testified that he wrote the letter containing the statement of which plaintiff complains.

"The testimony complained of was given by defendant when a witness in a judicial proceeding, in response to a question of counsel. The testimony was presumptively privileged and before this presumption can be overcome the plaintiff must show affirmatively that it was not pertinent and material to the issue. This plaintiff has not done."

Treatment of Arthritis

A woman who was employed as a lady's maid consulted a physician with respect to an arthritic condition of about two months duration. She attributed her condition to the fact that she had stumbled sometime before while coming down stairs and had wrenched her back. The doctor carefully examined her and found an indication of fever, tender, hot, swollen joints, especially the right knee and hip, left ankle, right wrist, and left meta-carpophalangeal thumb joint. He concluded that she was suffering from infectious arthritis. He treated her with salicylates alternating with neocinchophen. The doctor determined, that in order to seek all sources of infection contributing to her condition, her teeth should be examined. He had X-rays taken and referred her to an Oral Surgeon. The X-ray report indicated that certain of her teeth were dead and it was concluded that very probably they were the source of an aggravation of her condition. She had certain old bridge work in her mouth, and the removal of the bridge work and the dead teeth was advised by the Oral Surgeon. Such advice was confirmed by the physician. The patient thereupon consented to the proposed dental work and it was performed with no apparent ill effects.

Sometime later, the patient instituted an action against both the physician and the dentist in which she made the claim that the defendants were negligent in advising the removal of five of her teeth and the bridge work claiming that such dental work was entirely unnecessary. It was claimed that as a result of the extraction of the teeth and bridge work, the plaintiff sustained a severe, general shock to her nervous sys-

tem and was obliged to incur considerable expense in having the extracted teeth replaced.

Just as the case was about to be reached for trial, the attorneys for the defendant dentist disposed of the action so far as their client was concerned by a nominal settlement. An attempt was made on behalf of the plaintiff to bring about a further settlement whereby the defendant physician should make a contribution but no such arrangement was consented to on behalf of the physician and finally the plaintiff consented to discontinue the action so far as the physician was concerned.

Death Following Injection Treatment of Asthma

A young, married woman consulted a physician who specialized in the treatment of allergic diseases, complaining of difficulty in breathing. After a physical examination the doctor made a diagnosis of asthma and gave her certain pollen tests. Over a period of nearly two years he administered to her, at repeated intervals from time to time, subcutaneous injections of various pollen extracts prepared by him. No ill effects resulted from any of said injections and patient's condition of asthma was clearing up satisfactorily. Finally, the doctor in the usual manner administered to the patient an injection of 6 c.c. of tree pollen solution. The injection was made subcutaneously into the right buttock and there was no evidence of anything unusual about the injection itself. The doctor tested upon inserting the needle to find out that he had not struck a vein before injecting the fluid. As the patient was about to leave the treatment room, just after she had adjusted her clothes, she sat down on a couch and told the doctor that she felt badly. He helped her to lie down on the couch and as he did he noticed that she was having difficulty in breathing and that she apparently was becoming cyanotic. He made all possible attempts to revive the patient, including injections of adrenalin but the patient did not respond and in a few minutes died.

The medical examiner investigated the case and gave the cause of death as circulatory collapse and bronchial asthma.

An action was brought by the patient's administrator in which the doctor was charged with having negligently caused the death of the patient. The case came on for trial before a judge and jury. Plaintiff's witnesses testified that upon the occasion of an injection previous to the one preceding the patient's death, an injection had caused

a reaction consisting of vomiting and severe headaches. It was claimed that the patient had so informed the doctor, although he denied any such occurrence. This occurrence, according to a physician called as an expert on behalf of the plaintiff, was a warning signal to the defendant that further treatment should not be given or that the dosage should be reduced. The claim further was that the last injection was considerably stronger than any of the previous injections. A friend of the deceased, who had accompanied her to the doctor's office, testified that just before her death she exhibited

certain symptoms which were characteristic of an anaphylactic shock. The plaintiff's theory was that these symptoms indicated that the defendant had injected the substance into the patient's vein and thus caused death. Such manifestations were denied by the defendant.

At the conclusion of a five day trial the issues in the action were submitted to the jury by the Trial Court, and after some ten hours of deliberation the jury returned a verdict in favor of the defendant, thereby exonerating him of all charges of negligence and malpractice.

THE FIGHT HAS ONLY BEGUN

While it is true that the more frank discussion of syphilis in press and radio is "a considerable advance toward the goal of eradication of that disease," we must not "allow ourselves to be lulled into the complacent belief that the attainment of this goal is now an easy matter," declares Dr. Ezra A. Wolff, Chairman of the Editorial Board of the *Bulletin* of the Medical Society of the County of Queens.

The sophistry that we can rapidly eliminate a disease such as syphilis, for which we have a known etiology, reliable diagnostic criteria and a specific treatment, simply by educating the public to avail themselves of such medical knowledge, while pleasant to contemplate, he continues, does not bear up under critical analysis.

Examination of the individual points of this argument brings to light the rather disconcerting fact that none of them is as sound as we might desire. The establishment of the etiologic agent of a disease does not, of itself, necessarily lead to rapid elimination, nor even, in many instances, to marked reduction in incidence of that disease, as witness tuberculosis. Furthermore, different strains of the *Spirocheta pallida* may differ markedly in their action on their hosts, while different degrees of reactivity on the hosts' part may lead to extremely varied, and frequently obscure manifestations of the disease. The symptom-free, sero negative, passive female carrier of infectious spirochetes is but one bizarre clinical example explainable on the basis of such variable reactivity.

Diagnostic tests likewise leave much to be desired. Darkfield examination is a highly specialized procedure, has only a short period of real effectiveness, and can

hardly be expected to come into widespread use by the individual physician. Serologic tests are useless when they could be of greatest value—within the first ten days. They require, even in their simplest form, a considerably specialized organization and careful control in order to be even reasonably accurate. Universalization of their use would require, in the United States alone, their routine application to 7,700,000 annual hospital admissions of all kinds, to 3,000,000 new syphilis patients annually, of which 650,000 are fresh infections. Financial provision and personnel for such an undertaking are not to be had for the asking.

Treatment, properly applied, is approximately 80 per cent effective, but "proper application" requires persistence and co-operation on the part of the patient, overcoming of technical difficulties of administration and toxic reactions to treatment, and, sad to relate, bolstering of the knowledge of the average general practitioner concerning modern, accepted therapy.

That even education of the highest sort is not an impregnable bulwark against syphilis is attested by the all-too-frequent incidence of extragenital chancre in physicians, and by the infection of well-informed individuals whose education has been nullified by alcoholic excesses.

Such considerations as these, while not insurmountable, point at least to the campaign against syphilis as a necessarily prolonged and tedious one. They must not be allowed to create an attitude of futility. Contrariwise, however, they can be turned to a most useful purpose if they but act as a sobering antidote against the intoxicating opiate of overconfidence.

Across the Desk

The "Menace" of Automobile Trailers

NOW WE HAVE A NEW MENACE, a new worry, the automobile trailer. Our life, our health, our civilization, our sanity, our this and that, seem to be always "menaced" by something. If we were to believe all we hear, we should live in a perpetual fright, a continual tremor, with our knees playing a staccato tattoo like castanets. Reformers with furrowed brows scream that we must sterilize half the population or else in a hundred years we shall all be in jail or the madhouse. Thirty years ago "experts" said all the world's gasoline would be gone in ten years.

The latest peril to stalk us is the harmless-looking shed or shanty on wheels that trundles along behind the old car, jerking and jolting it this way and that over the bumps and around the corners. Lots of folks have had the idea that the trailer was a blessing instead of a curse, taking them away from home cares to the freedom of the open road, and gratifying the *wanderlust* that infects us all, from the freckled rascal who runs away from school for a day in the woods to the millionaire cruising the seas in his yacht. Now they are told that this is all a mistake.

A Two-headed Peril

Well, if the trailer is a menace, it looks like a full-sized one. Figures are presented to show that 400,000 trailers will be trailing along our automobile trails this summer, housing some 1,250,000 persons, most of them unconscious of the deadly peril to themselves and the rest of us, or perhaps inclined to treat it with a good-humored "yeah?" Miami alone is said to have 13 licensed trailer camps, with a population last winter of from 5,000 to 7,000 persons. If the peril is real, then, it is not something to scoff at.

The argument is that it is of two kinds—the danger that the trailerites will eat or drink things that are bad for them, and the danger that the garbage and human waste

tossed from the trailers in the twilight along the roadside will start local epidemics.

Let us examine these perils. The first one has nothing to do especially with the trailer. Our millions of motor tourists have been eating and drinking everything they could get, anywhere they could get it, for many years, from hot-dog stands, from "Ma's luncheonette," and from roadside farms and gardens, raided in the dark of the moon, without any widespread fatal results. Why will anything worse happen to them when they ride in the trailer?

Don't Forget the Domestic Animals

The other peril is the one that is stressed more gravely by our friends who feel alarm over the situation. The modern trailer is fitted with tight metal cans provided with chemicals which are said to disinfect the garbage and human waste thoroughly. As the trailers mount into the hundreds of thousands, the fear is that the disposal of more and more waste material will become a nuisance and a menace to health.

It is true, of course, that distasteful and unpleasant possibilities lurk here, but it may be equally true that we are needlessly alarmed. We are told that the reckless tossing of waste here and there will pollute the streams, overlooking the fact that practically all streams traverse lush and verdant meadows where the cows, horses and sheep show even less care than the trailerites about where they deposit their waste products. This has been going on for centuries, without eliciting any exclamations from guardians of the public welfare. Yet it is six of one and half a dozen of the other.

And when we come to the question of roadside deposits, we must remember old Dobbin, of horse-and-buggy days, who didn't even step to the roadside in his time of need. Streets with a large horse-drawn traffic were far worse than anything the trailers are likely to cause, all without any

outbreak of plagues or any outcry of alarm

Scared Before We Are Hurt?

So it is a question whether we are not scared before we are hurt. And even if our worst fears are well-grounded, we must remember our army of health officers, who are far from blind to this situation. Some state boards of health are contemplating the issuance of rules and regulations to cover health angles of trailers operating within their borders. The city and county of San

Francisco have issued a "Sanitary Code for Automobile Trailers," which could be copied to advantage by other towns. In one sense a trailer is a residence, and may be made to conform to local housing regulations of the town or city where it stops. At any rate, we can safely trust the vigilance of our health guardians to see to it that the fears of the alarmists are not realized, and, at the same time, if the warnings have helped rouse them to activity, we can admit that the alarmists after all have their useful place in the great scheme of things.

Birth of a Superstition

RURAL DOCTORS, and city ones too, meet strange superstitions—so fantastic, indeed, as to make one wonder how in the world they ever originated. In some parts of the South the dragon fly, which the children up here call a "darning needle," is known as a "snake doctor," and is supposed to minister healing to the cotton-mouth moccasin. The folks who believe that are equally sure that when bitten by a snake you should clamp on the wound the still-quivering halves of a young chicken which, while alive, has been split open with a hatchet or knife. Irvin Cobb relates this in his story entitled "Snake Doctor." Another superstition is that a porous white stone found in the bellies of rutting deer is the only cure for a mad dog's bite—clap it on the wound and it clings like a leech and sucks the poison out! If a snapping turtle closes his jaws on your flesh, he won't let go till it thunders. And so on and so forth.

How do these curious beliefs start? No one knows. But we do know the origin of a new one, playfully launched in an antic spirit by a Massachusetts physician who sends an account of it to the *New England Journal of Medicine*. He is Dr. Raymond R. Root, of Georgetown, who declares that "the tale is quite unvarnished" and "all happened exactly as related," and "might be used as an amusing explanation of the origin of the beliefs still prevalent even within a few years in rural New England."

The Story

It was Mrs. Reade's first baby, and the 80-year-old nurse, Mrs. Paine, was worried over the delay of the afterbirth. "Don't you

think its time it came?" she asked querulously every few minutes. "I imagine it will come along most any time now," the doctor would reply. Mr. Reade, short, cross-eyed and almost totally bald, fanned his wife nervously.

The doctor sat beside the bed, one gloved hand obscured in the folds of a sterile sheet on the mother's abdomen. He could easily keep informed of the contractions of the uterus while marveling at the gilt-framed chromo, sole work of art in this transformed parlor.

"Doctor, don't you think that if Mrs. Reade blew on the back of her hand it would make it come?" Mrs. Paine had remained silent as long as possible.

"No, I don't believe it would," replied the doctor. He knew from the condition of the uterus that the placenta had not become detached.

"Well, your father told me about that way more than fifty years ago, and I've seen it work a good many times."

"I know, but times have changed in fifty years, Mrs. Paine."

Silence for a few minutes. Then, "Well, do you mind if she tries it, Doctor?"

"No, go ahead if you want to, but it won't do any good."

Delighted to be in action again, Mrs. Paine instructed the willing patient in the exact manner of clapping her hands and how to blow on the back of one of them. All was ready, the patient blew hard and long, repeated the performance—all without result.

"You see, Mrs. Paine, it's just as I told you. Times have changed," said the doctor. Somewhat chagrined, she replied, "Well,

I've seen it work, over and over again I don't see why it doesn't now"

Mischief Germinates in the Doctor's Mind

While she was speaking, the doctor felt the uterus rise under his hand. He knew that he could probably express the placenta easily now.

"But I'll tell you what will bring it, every time," he said.

"What's that?" she asked.

"If the mother will blow on a bald head, the afterbirth will come every time. Never knew it to fail."

"You don't say so! I never heard of that," she said in an astonished voice.

"Well, it will," he replied.

"Why, look, Mr. Reade is baldheaded!" she cried.

"That's so, you're right," said the doctor, apparently surprised in his turn.

"Do you suppose it would work with him?" she asked.

"Don't see why not, he's certainly bald enough."

"Can we try it?" was the next question.

"Surely, if he's willing," agreed the doctor.

The new father proved more than willing to make an asset of what he had always considered a liability. He was carefully

instructed as to the exact position to place his head for easiest reach of the patient, while Mrs. Paine nearly lost her glasses trying to miss none of the technic at the head of the bed, which might be so helpful to her upon some future occasion, and at the same time to watch for results from this maneuver so new to her.

The Hokus Pokus Works

At last all was ready, and the patient blew directly at the bald pate. At the same time, with a motion imperceptible to all, the doctor's hidden hand pressed down firmly on the uterus.

Never was therapeutic effort more promptly rewarded. Cause and effect were here synchronous. And out popped Mrs. Paine's eyes, until it seemed they might push off her spectacles completely.

"Why, Doctor! I never saw anything like that in all my life," she exclaimed.

"Well, Mrs. Paine, you see now that we've made some progress in baby cases since you and my father started out nearly sixty years ago."

"Oh, if I'd only known about that all these years," she said regretfully.

"Well, you don't always find anyone as bald as Mr. Reade," the doctor consoled her, as he began to pick up his instruments.

WAS IT A CRADLE PHONE?

"Discovering that she was going to give birth before she could travel from her home to Chicago's Maternity Center, Mrs. Leonard Nelson telephoned there for advice. With the telephone receiver clutched to her ear, she then proceeded to do what the alert obstetrician at the other end of the line told her to do. After eight minutes of this Mrs. Nelson cried that she had

borne a son and started to hang up. A neighbor, however, snatched the receiver, yelled over the phone 'She's going to have a twin!' The doctor 'Let me talk to Mrs. Nelson again' For five more minutes Mrs. Nelson followed directions, bore her second son, sighed, 'Thank you doctor,' and hung up."

—*Time*, April 26, 1937

WHAT'S THE ANSWER?

"Great disappointment" is expressed by a prominent foreign woman physician visiting America because she finds that "fewer American women physicians than I had expected hold positions of honor in the medical world." She is Dr. Martha Bruenner-Ornstein, chairman of the Austrian committee at the recent International Conference on Fever Therapy, and one of the speakers at the meeting of the New York

Physical Therapy Society at the New York Academy of Medicine. She adds "We hear so much in Europe about the great opportunities for women in America that I had expected every woman of real ability here would have been advanced to distinguished positions. I thought about every other prominent doctor here would be a woman."

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

The Diagnosis and Treatment of Pneumonia. By Campbell P Howard, M D (Reprinted from Oxford Monographs on Diagnosis and Treatment) Octavo of 373 pages New York, Oxford University Press, 1936 Cloth, \$6 50

Howard's monograph on pneumonia, bronchopneumonia and common cold is one of the most outstanding to date, and richly

deserves its reprinting from *Oxford Monographs on diagnosis and treatment*

The subjects are thoroughly treated and the compilation of facts and the digest of literature soundly handled The bibliography is excellent

The chapter on prognosis may be cited as evidence of the broad sweep of the volume. Herein are discussed the factors of social

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W 42nd St., N Y C.) postage prepaid. Order must be accompanied by remittance covering published price.

status, residence race, sex, age ("The old are likely to die, the young recover"—Sturges), occupation, habits and disease, alcoholism, obesity, and certain symptoms and signs—high temperature, rising pulse, falling blood pressure, rising respiratory rate, cyanosis, leucopenia, extent of the lung lesion, complications, the acquired partial immunity of previous attacks, and the virulence of the infecting organisms with the persistence of blood stream infection

Thirty-two pages of the 256 are devoted to treatment. Serum receives the emphasis that it deserves. The use of digitalis is thus stated,—“only when heart disease co-exists or when auricular fibrillation or some other evidence of serious myocardial change has made its appearance”

Alcohol receives the following *coup de grâce* “It is valueless, if not actually harmful, except to the habitual user, when regular moderate doses may prevent the development of delirium tremens, which is more apt to be precipitated by the sudden withdrawal of all alcoholic beverages”

FRANK BETHEL CROSS

Medical Classics Volume 1, Number 1, September 1936. Compiled by Emerson Crosby Kelly, M.D. Quarto of 78 pages, illustrated. Baltimore, Williams & Wilkins Company, 1936. Paper

This is the first number of a new publication, which “aims to awaken the interest of all medical workers in the historical side of their profession. The work will be useful, not merely ornamental.” The subject chosen for this first issue is Sir James Paget and his original observations on Osteitis Deformans and Paget’s Disease of the Mammary Gland. The author has given us a fine monograph, with a portrait of Sir James, a complete biography, and the details, with illustrations and photostats of the distinguished surgeon’s original work. As time rolls on, this new venture must prove a great stimulus to others in the field and an invaluable contribution to the cultural side of medicine. We wish for it all success.

J M VAN COTT

Bailey’s Text-book of Histology (Elwyn and Strong). Ninth edition, revised and rewritten by Philip E. Smith, Ph.D. Octavo of 773 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$6.00

This edition has been revised by the Professor, and four of his associates, of the Department of Anatomy of The College of Physicians and Surgeons, Columbia University.

Several chapters have been completely rewritten, and notable reorganization of

content contrasts this with the previous issue. The relationship of histology as a structural science to unit physiology and pathology has been maintained, and the book as a whole retains its feature of clear presentation of facts and, when necessary, opposing views. With no wish to detract from its scope, as “Bailey” certainly is not a simplified textbook, we believe that its services as a reference in histology for practitioners would be further enhanced by the inclusion of references. Its general worth is well known and assures it a place in the library of most physicians.

IRVING M. DERBY

Eugenical Sterilization: A Reorientation of the Problem. By The Committee of the American Neurological Association for the Investigation of Eugenical Sterilization. Octavo of 21 pages, illustrated. New York, The Macmillan Company, 1936. Cloth, \$3.00

This collective study on eugenical sterilization was undertaken by a committee of five members of the American Neurological Association, who have aimed to investigate this moot topic not as eugenic idealists but as critical practitioners. After a lengthy introductory consideration of the individual laws of each state, and the familiarly known arguments for and against sterilization, as well as the attitudes of different religious sects, the authors then proceed to the really difficult problem to which they were assigned. And whereas the real proof for their contentions may be the subject of controversy because the data is too generalized, they have raised a real issue which deserves the attention of eugenicist and clinician alike. Whereas formerly eugenics was beyond the scope of the clinician, it has now made its inroads through the negation of supposedly scientific data. In everyday parlance, it would mean gaining entry through the back door.

This group of physicians contends that eugenics has received scant support on any basis from genetics. They maintain that heredity in mental diseases cannot be classified on Mendelian principles especially because the most common psychiatric disorders are not clinical entities. Dementia precox is typical of these. Then again, diagnoses among different observers vary widely. Moreover, the genetic approach to crime has been unsatisfactory, because of the definite influence of education, training, and better health and economic conditions in the prevention and control of crime. And as long as human conduct and character are matters of too complex a nature, sterilization should be recommended only for

cases which cannot be controlled through other means

EMANUEL KRIMSKY

Diseases of Infancy and Childhood By Wilfrid Sheldon, M D Octavo of 738 pages, illustrated Philadelphia, P Blakiston's Son & Company, Inc., 1936 Cloth, \$7 00

Sheldons' book is written in the typically interesting British manner. It accomplishes quite well the author's purpose to make it more than a handbook of pediatrics and still not compete with larger works of reference.

We found it interesting more as the exposition of a skilled pediatrician's views on the whole general field of pediatrics than as a specific contribution of special merit.

CHARLES A WEYMULLER

Dietetics for the Clinician By Milton A. Bridges, M D Third edition Octavo of 1055 pages Philadelphia, Lea & Febiger, 1937 Cloth, \$10 00

This is the third edition of a volume which has found great favor with the medical profession.

The material assembled is physiologically sound and thoroughly practical. The author has added an important chapter on the analyses of food in the edible state. The literature on diet therapy has been extensively reviewed and the author has made a survey of the various dietary fads.

Recognized specialists in their respective fields have contributed to the excellence of the volume. This present edition should be of value, not only to the general practitioner, but to those employed in the dietetic departments of hospitals and clinics.

This book should meet with the enthusiastic approval of all

IRVING GRAY

Physical Diagnosis By Ralph H. Major, M D Octavo of 457 pages, illustrated Philadelphia, W B Saunders Company, 1937 Cloth, \$5 00

The illustrations in this work are many and excellent. The author's frequent reference to original descriptions of the masters, Biot, Skoda, and many others, make it most interesting. The book stresses and proves, in this age of apparatus, the fundamental importance of inspection, palpation, percussion and auscultation. The chapters on the heart, pulse and cardiovascular diseases are extremely interesting.

This book is indeed timely and is not only an invaluable aid to the student who will be stimulated to read and study the works of the old masters, but is also of equal importance to all practitioners of medicine.

CHARLES SHOOKHOFF

A Synopsis of Surgical Anatomy By Alexander Lee McGregor, F.R.C.S. Third edition Duodecimo of 664 pages, illustrated. Baltimore, William Wood and Company, 1936 Cloth, \$6 00

This is the third edition of a work which was first presented to the profession in 1932 by Dr McGregor and is essentially the same as the second edition, except that more data relating to nerves of the thyroid and adrenal glands has been added. There is also a more detailed description of hernia of the diaphragm. New terminology is used throughout the volume. This book fulfills in an excellent manner the object of the author, that is, practical anatomical facts for student and practitioner.

Black and white illustrations cover practically the entire book. It is divided into two parts, the first dealing with the normal and the second with the abnormal. This arrangement begins with the head in each part and goes on through the body, thus making an excellent opportunity for the reader to correlate the normal with the abnormal. The last chapter is an exceptional one where the author takes up in a practical way the anatomy of surgical approach.

One criticism that might be made is, that the text for the most part is too small for comfortable reading. The concise manner in which the black and white drawings have been executed adds a great deal to the work. This volume should be an asset both to the student and to the practitioner.

HEBERT T WIKLE

Childless A Study of Sterility, Its Causes and Treatment. By Sam G. Berkow, M D Octavo of 307 pages, illustrated New York, Lee Furman, Inc., 1937 Cloth, \$3 00

This is a popular Science treatise, not a sex book, which discusses sterility and the biochemistry of fertility. Normal forms are described, as well as various types of abnormal forms, such as gigantism, dwarfism, cretinism and the like, with their background and importance as factors in the problem of sterility given proper weight. All are warned of the dangers of birth control and abortion. That part of the public which is fortunate enough to be somewhat above the average educational level will find this a very interesting book. The author's style is smooth and liquid and his science sound.

This book is a welcome addition to the public's popular science library, and is absolutely free from the objectionable features so commonly found in these books today. Physicians without special knowledge of sterility will enjoy this book.

THE SEQUELAE OF HEAD INJURY

ISRAEL STRAUSS, M D and NATHAN SAVITSKY, M D, *New York City*

We have discussed the subject of head injury in previous papers^{8,9}. In this paper we desire to make further comments on the subject of sequelae of head injury exclusive of traumatic epilepsy.

Until very recently, the problem of the remote consequences of head blows was sadly neglected by physicians. The alarming number of industrial and motor accidents has, however, resulted in a striking increase in the incidence of persons suffering from the effects of head trauma. The socio-economic implications of this problem are evident and the question of the evaluation of the clinical significance of the residuals of head trauma is engaging the attention of many investigators throughout the world.

The lack of thorough clinical investigation of the injured immediately after the accident has added to the difficulties inherent in the problem.¹ The injured are usually admitted to surgical wards where they are examined by physicians whose interests lie mainly in surgical therapy and management. These physicians have neither the time nor the training to study the patient carefully from the neurologic and psychiatric standpoints. There is no doubt that expert opinions regarding the meaning of the sequelae of head injury would be modified if it could be shown that immediately after the injury there was ample evidence of focal injury to cerebral tissue. The few autopsies obtained in patients who died from other causes long after a head injury have illustrated

the surprisingly extensive destruction of cerebral tissue with minimal or no clinical evidence of focal disease. A fair decision as to the meaning of these remote syndromes cannot be made without an accurate study of the patient during the first few days after the accident. An instructive example is that of a patient examined nine months after a severe head injury in whom a definite right homonymous hemianopsia was found. When the hospital records were examined there was no mention of this extremely significant finding. In the absence of other causes the examiner was forced into the position of correlating this present symptom with the other clinical changes and postulating that it was due to brain destruction at the time of the injury. On the other hand it might be objected, and justifiably so, that this condition may have been due to some unrelated cause or even to a second accident. In such a case a fair decision is difficult to make. This example is not at all exceptional.

The search for objective signs of focal and more diffuse injury to the brain continues.²⁻⁴ This emphasis on the importance of objective findings in forming an opinion regarding seriousness of injury is due to a pernicious though inevitable effect on our medical thinking of legal procedure and rules of evidence. They should not play so important a role in medical practice. The total behavior of the patient, his ability to think, his attitude towards reality, his affective re-

Address by Dr Israel Strauss at the Annual Graduate Fortnight of the New York Academy of Medicine, October, 1936

sponses, as well as the numerous subjective complaints are just as important in determining our diagnoses and opinion as mild reflex changes, disturbances in pupillary reactions or dyskinetic phenomena. There can be no doubt that many physicians prefer to use these objective neurologic signs as criteria of seriousness of injury because they are more practical, much easier to determine clinically, and do not require elaborate investigations and study. Such an attitude on the part of the examining physician is often obviously a defense reaction because of his ignorance of functional, psychic disorders, and his unwillingness to acquire the knowledge necessary to a proper handling of such problems. It is distinctly unfair to state that a patient has no thinking difficulty and that there has been no dilapidation of his personality because we are either too busy or not interested enough to spend the necessary time to establish such facts. The philosophy of the seeking for objective criteria needs a radical overhauling.

Because accurate neurologic studies of the injured before the accident are rarely available, great caution must be exercised in the evaluation of a particular objective sign which may very well be the sequel of numerous other noxious agents to which the individual may have been exposed throughout his life. A diminished ankle jerk may have been due to an old mild sciatic neuritis and a pathological reflex the result of a transitory encephalitis during an infectious disease of childhood. We are forced, therefore, in our ultimate decision to emphasize the importance of disturbances in total behavior, of alterations in the individual's ability to grapple with real problems and adjust at his previous level. The materialism of recent medical thinking and the reflexological tendency in clinical practice are evident schematizations and oversimplifications of the complex problems before us.

Further study of the post-concussion syndrome has confirmed its validity.^{6, 8} This symptom complex was originally described by Friedman in 1892 and its clinical significance emphasized by Pierre Marie⁷ in 1916. In our previous communications^{8, 9} we merely re-emphasized the importance and reconsidered the significance of this subjective syndrome following head blows. We stressed especially

its differentiation from the psychogenic response to trauma. The headaches in the post-concussion syndrome are usually true pains or aches, recurring paroxysmally, and becoming definitely worse in reaction to mental and physical effort and during inclement weather. These pains usually become less intense and recur less frequently as time goes on. They are often intensified by radical alterations in the position of the head and body. Attacks of unsteadiness and occasionally true vertiginous experiences may or may not be present. Ready fatigue, varied ocular symptoms, irritability, and emotional instability are almost always present. Discomfort with conjugate lateral or upward gaze is characteristic. The psychogenic headaches are usually described as sensations of tightness or constriction in the head and occasionally as burning paresthesiae. They are much less paroxysmal, are closely related to alterations in mood, and often become worse as the personal and socio-economic difficulties increase.

It must be borne in mind that the post-concussion syndrome is a purely clinical concept referring to the frequent persistence of subjective distress following a concussion. The term concussion itself is very unclear, but has for centuries been used to designate what happens to the brain following severe injury when no evident morphologic changes in that organ take place. There are only a limited number of ways in which the brain as other organs can react to trauma of any type. The only way in which the brain as a whole can respond to severe trauma is by loss of consciousness. The physiologic and morphologic changes may be very different though the clinical pattern is identical. A concussion in one case may be associated with numerous petechial hemorrhages, in another diffuse edema of the cerebrum, in a third significant interference with cerebrospinal fluid hydrodynamics, in a fourth widespread vaso-spasms with impairment of circulation and in others by a marked subarachnoid hemorrhage. In some cases multiple small contusions in silent areas of the brain are undoubtedly present.

If we are to continue using the term concussion we must bear in mind its limitations. Many have recently objected to its continued uncritical use.¹⁰ Every effort

should be made to determine as precisely as possible just exactly what happens in the particular instance of head injury. In such clinical investigations one must not forget that reversible alterations in functions and persistent physiologic disorders without gross tissue changes may exist and account for the distress of the injured. The demand of those schooled in the Virchow theories of pathogenesis for a morphologic substratum for all disease entities is no longer justified. Vasospasms, changes in tissue irritability, disturbances in meningeal permeability, and cerebrospinal fluid production are as important as the small hemorrhages, focal lacerations of brain tissue, and edema of the brain.

The encephalogram has been of some help in the study of the sequelae of head injury. It has proved especially useful in the diagnosis of those cases of traumatic epilepsy in which a retracted scar has caused homolateral dilatation of the ventricular system with a pulling of the ventricles towards the side of the lesion. The evaluation of the other changes must await the accumulation of more control observations. The normal range of variations has not yet been satisfactorily established. The encephalogram of older individuals is not that of the younger adult. Undoubtedly many errors in interpretation have been made through variations in the technic used by different observers. More rigid observance of a standardized technic is extremely essential. We are convinced that a revision of opinion is necessary in certain cases in which we previously stressed the significance of the presence of large accumulations of air over the cortex of one hemisphere or both. These aerographic changes are probably due to occasional collections of subdural air which one sometimes sees in normal individuals. The presence of this air is unquestionably due to some fault in technic, and no clinical significance should be attached to its existence. Pre-existing and previous disease such as transitory hydrocephalus, arteriosclerosis, and old unrecognized injuries make the interpretation of the encephalogram in the injured individual a difficult problem. The normal encephalogram does not at all rule out even diffuse intracerebral changes. The repetition of the encephalogram during the course of a protracted post-traumatic syndrome may

throw light on the pathogenesis of some post-traumatic complaints. This can only be of value if the same technic is used throughout. Like all instruments of precision it should be used judiciously. The aerograms must be considered in the light of the total clinical picture. It is evident that some clinicians have overemphasized the value of the encephalogram in the interpretation of the post-traumatic syndrome.¹¹ Lippens and Dejardin present two cases with similar complaints and reject one of them because the encephalographic findings are negative. Such a conclusion based on encephalographic findings alone is untenable. The encephalogram by itself should no longer be the deciding point in the crystallization of the opinion of the expert.

We objected in previous studies to the use of the term traumatic neurosis. It is, however, a convenient designation if it is used only as a generic term to include the wide range of psychogenic reactions to trauma and its sequelae. There is no characteristic traumatic neurosis. There is no neurotic symptom-complex which is found only after trauma to the head. The organic subjective symptom-complex which some have been calling the post-concussion syndrome has been erroneously called traumatic neurosis. The nature of the neurotic symptom formation in the particular case varies and depends partly on the premorbid makeup of the injured. The trauma may cause an acute reactive transitory terror neurosis or it may precipitate a psychoneurotic syndrome which may last for many years. The trauma may reanimate infantile memories and complexes and perhaps even by its organic effect on the brain interfere with successful repression. This often permits the emergence into consciousness of significant subconscious constellations. The neurotic syndrome in these cases is an effort on the part of the psyche to defend itself against anxiety. Careful study of neuroses following trauma reveals every type of reaction encountered in nontraumatic practice. We have observed phobia formation and obsessive thinking appear immediately after a head injury in individuals who showed no tendency to neurotic symptom formation before the accident. The most frequent reaction pattern is undoubtedly that of hysteria. The coex-

istence of hysterical manifestations and organic sequelae has been present in a very large percentage of the cases that have come under our observation. Such concomitance of psychogenic and organic sequelae creates a clinical picture which is often quite complicated.

We have on a number of occasions noted the persistence of the organic and the disappearance of the hysterical manifestations after a satisfactory money settlement was made. This was especially striking in a previously reported case of traumatic alexia with superimposed hysterical sensory changes. Such a course of events does not indicate that the desire for compensation was the only cause for the existence of the psychogenic symptom complex. It does show that removal of secondary gain in illness facilitates and hastens the healing of the psychogenic reactions to trauma. The persistence and even intensification of psychogenic symptom complexes after unusually satisfactory money settlements, although less common, is occasionally seen. We previously recorded such a case¹² and have since encountered others. In these cases the injury interfered with hitherto successful intrapsychic adjustments. Some type of equilibrium was destroyed making it necessary for the injured to resort to neurotic symptom formation. In spite of the unquestionable existence of other determinants one cannot deny the role which the trauma played in the development of the neurotic reactions. Among several striking instances we will cite the following example.

A forty-two year old housewife was seen for sudden complete weakness of the right upper extremity of two days' duration and double vision for one day. This diplopia did not disappear when one eye was closed. She had been in an automobile accident six months before. She was thrown forward and hit her lip against the handle which opens the windshield. She was then thrown backward and towards the side of the car striking the window frame of the door with her head. There was slight bleeding from the nose, contusion in the occipital region, and ecchymoses around the right eye. Double vision which followed the accident lasted for six weeks. Numbness of the right side of her body and head appeared after the injury with weakness of the right side of the body which persisted and had been becoming worse before the sudden complete

loss of power in the right upper limb. The examination showed a functional hemisensory syndrome on the right side with monocular diplopia. All the special senses on the right side were also involved. This progressive intensification of a hysterical syndrome came on after a very satisfactory settlement had been made. There was no pending litigation and no possibility of reopening the case.

Psychological study of this woman revealed many personal difficulties and frustrations. The nature of this continued intrapsychic turbulence has no bearing on the point which we would like to re-emphasize. These same problems confronted this woman before the accident. She was able to rally more normal defense mechanisms and apparently adjusted without any neurotic symptom formation. In fact fifteen years before she was seen, her children, husband, father, and mother were killed in an automobile accident and nothing unusual happened to her at that time. How can one deny that the injury to her head played a very significant part in the appearance and the persistence of severe hysterical symptoms even after an adequate money settlement?

The injury not infrequently impairs the individual's ability to tolerate and adjust to difficult situations. We had the opportunity of studying a man who dramatically insisted on his inability to remain in his home and continue living with his wife. Domestic infelicity based on conjugal incompatibility had been present for a long time. He was, however, able to more or less contentedly live at home. He found it impossible to continue in the same way after the injury. His anxiety at home was most intense and his hostility to his wife often resulted in assaultive behavior which ultimately made a separation necessary. The existence, therefore, of problems and personal difficulties before the accident does not invalidate the theory that the trauma, either by its organic or psychic effects can alter the individual's ability to handle them as adequately as before the injury. It is occasionally difficult to differentiate this impaired ability to solve one's problems, undoubtedly related to the injury, from the not infrequent capitalization of the injury to further other psychic ends. This latter reaction pattern borders very closely on malingering. An incompetent person hides behind an injury, accounting in this

way for his repeated failures, a neglected wife exaggerates her symptoms to recapture the affections of her husband. We recently studied the case of a man who following an industrial injury failed to improve though there was no monetary gain in further illness. This man apparently clung tenaciously to his symptoms because they made his adjustment to a distressing sexual impotence much easier. We believe that such capitalization of existing defects and symptoms because of their psychic economic value may take place subconsciously. It may take a long time to give these patients insight into the purpose of their continued invalidism.

Deliberate and conscious simulation and exaggeration of symptoms to aid in adjustment does also take place. In such instances we are dealing with malingerers. The injured will often seize the opportunity of obtaining money to help him out of financial straits. In these instances the cases should be settled only for the injury sustained. The nervous symptoms are unrelated to the accident.

The problem of the interference with existent compensatory mechanisms by trauma to the head has received very little attention. The capacity of the organism to adjust to psychic and somatic defects is striking. Refractive errors are overcome readily by more intense activity of the accommodating mechanism so that correction by glasses may not be necessary for a long time. A woman of forty-nine had to be given a pair of glasses to aid her vision for the first time after a moderately severe head injury. We have observed many instances of those who after a head injury became again aware of a hearing defect and even tinnitus due to an old ear infection. The most instructive instance of impairment of such a compensatory process was that of a twenty-seven year old painter who began to stutter immediately after his head was injured in an automobile collision. He was a left handed individual who had no difficulties in speech, reading or writing up to the time of the accident in spite of the fact that he had been forced to use his right hand all his life for writing and other dexterous movements. He was able in some way to master the difficulties which unquestionably accompanied this change of dominance. He was no longer

able to do so after the blow to his head.

Investigators of the subject of the neuroses following trauma frequently allude to the observations on the war neuroses to support whatever contentions they hold. We have previously commented on the fallacy of comparing war experiences with head injuries and the traumatic neuroses of civilian life. The simultaneous exposure of thousands of individuals to an identical constellation of harrowing experiences permitted the accumulation of valuable observations as to what happened to that large group of human beings under the particular circumstances. We wish to repeat that these war experiences cannot in any way serve as a control study. While the morbid manifestations of the war neuroses and the psychogenic reactions of civil life are similar the problems of psychogenesis are not at all comparable. Control studies of the natural history of the neurotic reactions in civil life are lacking. In evaluating the individual problem in private practice one has, therefore, to call upon one's own experience. We must give up this tendency to call upon the war experience in the interpretation of neuroses of civil life.

There is also no question about the fact that litigation is an added strain and undoubtedly tends to aggravate neurotic symptoms. Under our legal system the injured is unfortunately burdened by the necessity of defending himself against those who oppose his claims. He is supposed to be a plaintiff although he is really a defendant. It is inconceivable that any normal human being should not react unfavorably to this well-known complex of disturbing influences popularly known as a trial. The so-called litigation neuroses is a fiction. What is commonly called litigation neurosis is really malingering. If simulation does not exist we are dealing with a true neurosis perhaps aggravated by the litigation. Neurotic symptom formation is an unconscious response to intrapsychic maladjustment. The stress and strain of the trial is only one of many etiological factors. It is astounding to note the persistent prevalence of the notion that malingering is synonymous with the unconscious psychologic response to trauma.

The physician cannot and should never play the role of prosecutor or detective,

bent on uncovering intent to defraud. Such an attitude impairs the desired rapport between the physician and the injured and precludes successful treatment. It engenders resentment in the patient and encourages the flowering of psychogenic complications. The expert's opinion is based on evidence presented to him. He is very often not in a position to verify whether the injured was unconscious or did vomit after the accident. Such checking up of facts should be done by other agencies. The expert should readily alter his opinion if new, significant anamnestic data is presented to him. He also cannot but avoid the impression which the total behavior of the patient makes upon him. The accuracy of such an appraisal must depend on the keenness and experience of the particular physician. Hard and fast rules which will aid the tyro in detecting the simulator can hardly be made. Our added experiences since our last published studies confirm the previous impression that true malingering is extremely rare though exaggeration is not uncommon.

It is important to stress the fact that adequate motivation and incentive to ignore discomfort may operate unconsciously to raise the threshold for pain and distress in a particular individual. The polo and football players are pointed to as examples of those who in spite of severe head injuries rarely have the characteristic post-concussion syndrome. In the first place no accurate statistics are available indicating the percentage of these athletes who have no complaints following severe head blows. The isolated case is emphasized. There are unquestionably similar cases who are injured during work but who never report the injury and continue to work in spite of distress. The compensation physicians encounter only those workers who complain. In the second place it is important to emphasize that some individuals if adequately motivated can ignore even very intense subjective distress. The desire to be hailed as a hero and to avoid the opprobrium of being considered a complainer are relatively powerful determinants of the conduct of these athletes. They are bred in an atmosphere where the ability to suffer without complaint is praised. These demands of the social milieu of the injured

athlete have a significant effect on the threshold for pain. The injured football player has to choose between somatic discomfort and ego frustration. He usually chooses the former.

The following case illustrates the inaccuracy with which information regarding injured athletes is gathered.

A twenty-one year old college student was seen complaining of headaches and dizziness since an injury to his head during a football game one day before the examination. His head struck that of another player. Though there was no loss of consciousness he was confused for a short period following the impact. He vomited immediately after the accident. No evidence of focal injury to the nervous system was found. He told of another football injury four years before during which he was severely hurt. He bled from the nose and mouth at that time. He remained in a hospital for about thirty-six hours. He continued to have paroxysmal pains in the head up to nine months before the second accident. Dizziness with change of position persisted up to two days before the second injury. He did not report this continued subjective distress to the university physician or his athletic advisors. He admitted very readily that he was motivated by a desire not to be excluded from participation in football activities. He would not have been permitted to play until he was entirely free of post-traumatic symptoms.

The repeated assertion that the injured always deliberately exaggerate can only be made by those who lack understanding of the intricacies of the psychic mechanism. The subliminal and subconscious nature of many of the psychological processes involved in the reaction to trauma are not recognized sufficiently. The assumption that the average working man seeks consciously to lengthen the period of his disability to obtain money without working is not borne out by our experience. The monetary gain in illness is in most cases hardly sufficient to warrant such behavior in normal times. The role of the profit-motive in determining the conduct of the workman and those injured in industrial accidents has been overemphasized. Everybody seeks a state of well-being, and the forces impelling one in that direction are usually more powerful than temporary economic security. It must be admitted that in times of unusual economic insecurity the secondary gain in illness, the profit-motive may be of more

significance than at other times. It would be very illuminating to study the records of post-traumatic syndromes in the files of the Compensation Commission to compare the course of the cases during depressions with those seen during periods of relative prosperity. It must be re-emphasized that while intensifying the symptoms it is rarely the sole cause of their appearance. While it may lead to prolongation of illness, it is not the primary cause of the development of the neurosis.

The question of the differences in response to similar injuries has added to the perplexities of the problem before us. In evaluating an apparently serious response to a relatively minor injury one must take cognizance of the premorbid organization of the injured. While injuries may be approximately similar the precise dynamics of the nature of the impact of the head with the solid object may differ. One can very rarely accurately reconstruct exactly what happened during a particular accident. There are too many variables involved. It is occasionally difficult to explain why severe and incapacitating post-concussion symptoms follow relatively mild head injuries.

The relation of head trauma to brain tumor and general paresis deserves some comment. No cogent proof has yet been offered of a causal connection between trauma and brain tumor. In spite of the numerous reports in the literature emphasizing especially the aggravating role of head trauma in brain tumor and dementia paralytica, we have not been able to accept the hypotheses offered by these investigators. One cannot avoid the impression that in most cases the injury is entirely coincidental and that often the pre-existing tumor was responsible for the accident. The statements that the injured were perfectly well before the head trauma cannot be accepted as proof of the absence of intracranial pathologic changes. Very few of these claimants had been examined by competent neuropsychiatrists. Any other proof of the patient's being perfectly well cannot be accepted. Both brain tumor and general paresis may have an acute onset without any trauma in patients who had adjusted perfectly well up to the onset of the illness. The absence of increased incidence of brain tumor and

general paresis in large series of head injuries which have been followed confirms the clinical impression that no causal relation has as yet been established between head trauma, general paresis, and brain tumor.

The treatment of the sequelae of head injury is a sorely neglected subject. The injured are examined and re-examined. Signs of improvement or aggravation are noted carefully. Questions of disability are elaborately considered and discussed in conference. Relatively little attention is paid to the problem of the amelioration of the distress of the injured. They can be made much more comfortable and they clear up more rapidly when attention is given to the problem of therapy. An initial period of rest following every head injury is important. We have noted for a long time that those who have longer periods of rest immediately after the injury have less severe and disabling post-concussion syndromes. The headaches are not marked when the patient rests. Symptomatic therapy is indicated. Mild dehydration sometimes helps. When the headaches become particularly refractory a lumbar puncture should be done. The lumbar puncture occasionally rules out other coexisting organic disease. The patient is sometimes relieved by the removal of spinal fluid. We have repeatedly seen patients who had almost intolerable headaches for months completely relieved by the removal of ten or fifteen c.c. of spinal fluid. In some cases the endolumbar injection of air as recommended by Penfield results in gratifying alleviation of symptoms.

Psychotherapy is a very important adjuvant. The workman should be assured and reassured very early during the course of his illness that he has not sustained a severe injury to the brain. Investigations regarding the validity of claims should be made as speedily as possible and compensation due to the injured should be given without unnecessary delays. The examiners for carriers should treat the injured with as much care and consideration as they accord to those who come to them in private practice.

Attention should be paid to the personal life and problems of the injured and advice should be given to them if necessary. Occasionally the solution of some

other problem which intensifies the post-traumatic complaints may result in rapid recovery

In following the head injury one must be careful not to miss the occasional case of subdural hematoma. If headaches become unusually refractory; if the patient appears dull and somnolent, if weakness in a limb appears, and especially if a slow pulse is present with these symptoms, the patient should be hospitalized for further investigation. In the examination of large numbers of these patients the physician

will occasionally miss this type of case unless he is on his guard

The whole subject of trauma and the nervous system needs considerable housecleaning. We must divest ourselves of prejudices. Schools of thought have no place in medicine. We should all belong to one school whose aim is to seek the truth and alleviate the suffering of the injured.

"PART-TIME DOCTORS" IN THE SCHOOLS

Denouncing the present health service for physical defects among school children as "inefficient and ridiculous," Professor Jesse F. Williams, of Teachers College, Columbia, urges the employment of specially trained child health examiners rather than "part-time doctors."

Dr. Williams, who is chairman of the department of physical education, spoke at the annual conference of the American Physical Education Association in the Pennsylvania a few weeks ago.

"Part-time doctors," he said, are merely interested in "temporarily supplementing their incomes." These physicians, for the most part, he said, fail to "study the school problem, develop a professional attitude toward it and realize for children the full possibilities inherent in the service."

The ordinary physician lacks special training necessary for the job, because medical schools emphasize the diagnosis and treatment of a disease instead of preventive medicine," he said.

"For this reason it appears that a new worker is needed in the schools who will

be trained to recognize signs and symptoms of disease and defects and who will have the responsibility for conducting educationally sound health examinations. Such a person could be prepared in two years of a four-year undergraduate course."

Dr. Williams foresaw difficulties in the way of adoption of his plan, criticism by the medical profession and State laws that restrict health examinations to physicians.

But, Dr. Williams asked, "What is the sense of using someone in the schools who has spent all his professional training in learning things that don't function in the work he does, such as gynecology, obstetrics, pharmacology, legal medicine, microscopic diagnosis, surgery and pathology?"

Although the examination of children is now "miserably" done in the schools, Dr. Williams said the use of medical and surgical service is "even more unsatisfactory."

However, he added, with the health examiner plan in operation social health services for certain children could be inaugurated.

Dr. Irving Busch, of New York, has gone to Spain to relieve Dr. Edward H. Barsky, also of New York, as chief surgeon of the

American hospital established in Spain by the Medical Bureau to Aid Spanish Democracy.

SYRINGOMYELIA TREATED BY X-RAY

M B RADDING, M D, *New York City* and J A FORESTIERE, M D,
West New Brighton

From St Vincent's Hospital, West New Brighton

Syringomyelia has generally been considered a hopeless condition, and amenable to practically no form of treatment. The efficacy of roentgen ray therapy in this disease is not generally appreciated by the profession. Articles on this subject have appeared but little in American literature and almost exclusively in radiological journals. We have found this treatment to give a very gratifying result in a case as herein reported, and feel that its value should be brought to the attention of the profession at large.

Syringomyelia is a disease of the spinal cord characterized by dissociation of pain and temperature sensation, together with muscular atrophy. The latter usually begins in the interossei muscles of the hand since the cervical involvement is most common. It is a chronic progressive disease presenting a large variety of clinical syndromes since it may involve any part of the cord and medulla extending at times even to the pons, midbrain, and cerebrum. The cause of death is more often an intercurrent disease, tuberculosis having the greatest incidence. Because the sphincters and bladder are involved in the lumbar type, retrograde pyelonephritis is a frequent cause of death. Destruction of vital centers in the bulbar type with resulting death is rare. It must be differentiated from multiple sclerosis, amyotrophic lateral sclerosis, tumors of cord with spastic paraplegia, progressive muscular atrophy, central myelitis, syphilitic meningomyelitis, polyneuritis, leprosy, pellagra, Raynaud's disease, and ergotism.

The pathology is one of proliferating gliosis, with cavitation caused by softening of the central mass of glial cells. It may be limited, producing central gliosis, or infiltrative, resulting in diffuse gliosis. The cavity is usually posterior, small or large, single or multiple, sometimes extending

tending from equina to pons. It can be empty or filled with fluid which may or may not be under pressure. The thickness of the wall varies in different cases, in different segmental sections, and different cystic cavities of the same case. It is not believed to have any genetic relation to the central canal, hydromyelia having a uniform lining of ependymal cells. It must be differentiated from cavities due to hemorrhages—hematomyelia.

The effect of x-ray on young proliferating cells and on the vascular supply of tumors is well-known. The exact action in syringomyelia has not yet been explained. The glial cells are a young and almost undifferentiated form of embryonal tissue. Since these cells are overproductive in syringomyelia, they might be expected to be sensitive to the destructive effects of the roentgen ray. The other effect of radiation on this disease may be through its sclerosing action on blood vessels, thereby decreasing the vascular supply in the affected tissues. By these effects, radiation arrests the progress of the disease, and thereby decreases pressure on adjacent neurons and relieves irritation or destructive effects on them. Irradiation of cystic cavities may at first aggravate the symptoms, but on continuing the treatment, relief of symptoms appear. Clinical improvement appears first in the areas last involved because the neurons of these areas have been least affected. Where tissues have been destroyed, they are not regenerated.

Why pain fibers are restored more readily than temperature sensation cannot be explained, but it is a fact that while other cutaneous sensibility is re-established, temperature sensation is sometimes slowly or not completely restored.

Case Report

H V, colored, female, age thirty-nine, was admitted November 4, 1935

Dr Radding is instructor in Radiology, NYU Medical College.

Her chief complaints included weakness, difficulty in walking, and pain in back. Patient has become progressively weaker in the past six months. Her grip has become progressively weaker in the past six months. Her grip has become so bad that objects fall out of her hands. Four months ago, began to experience difficulty in walking. She attributed this to her weakened condition. Her difficulty in locomotion has become rapidly worse so that now she is forced to spend most of her time in bed. Her legs are stiff when she attempts to walk and she has trouble in keeping her equilibrium. Patient has complained of pain in the small of her back for the past two years. Pain at times is shooting or boring in character and is ameliorated by exercise. Her teeth had been previously extracted in an attempt to remove focal infection and thereby to relieve her back pain. Dyspnea and palpitation on exertion. No ankle edema. Dysuria in last four months.

Her past history was irrelevant. Had eight children. No miscarriages.

Physical examination revealed a well-nourished, colored female, weighing 134 lbs. Heart and lungs negative, pupils round, equal, react to light and accommodation, no nystagmus, extraocular movements, no facial weakness, tongue in midline, no rigidity of neck, abdominal reflexes absent, paresis of both hands, atrophy of interossei muscles, temperature and pain sensation increased in fingers, hands and forearms, more so on the left side, pectoral, triceps, biceps, ulnar, and radial periosteal reflexes bilaterally hyperactive and Hoffman sign positive, all reflexes of lower extremities are exaggerated, Babinski positive, Romberg negative, muscle, tendon and joint sense intact, more sensitive to pain on the right side, temperature sensation markedly diminished in the entire left calf, vibration decreased, indefinite area of hyperesthesia in supraspinatus areas beginning at level of second thoracic spine.

Laboratory

Hgb seventy-four per cent, erythrocytes 4,270,000, leukocytes 4,750, polys seventy-three per cent, lymphocytes, thirty-two per cent, monocytes four per cent, eosinophiles one per cent.

Urine albumin 2+, granular casts. Blood Wassermann 1+, repeated twice, negative.

Spinal fluid crystal clear, pressure twelve cm water, with jugular compression rises rapidly to sixteen cm, five cells per cmm, globulin increased, Wassermann negative,

colloidal gold curve negative, sugar 0.43 mgm.

X-ray of cervical, dorsal, and lumbar vertebrae negative.

Treatment

Patient received thirteen applications of 150 r each within a period of sixteen days. They were given to alternate sides of the posterior cervicodorsal spine, the beam being angulated toward the midline. Each portal was eight X thirty cm. The other factors were 200 KV, filter 0.5 mm Cu and 10 mm Al, FSD fifty cm.

Improvement began to appear after the first week of treatment. On May 6, 1936, patient was able to walk about without much difficulty although gait was still somewhat spastic. All reflexes were less hyperactive. Babinski reflex was now absent. Superficial abdominal reflex present. Paresis of hands had disappeared and patient was able to take care of her household duties. Sensation of pain had returned, temperature not completely, especially in fingers and left calf. On July 26, patient was again seen. She was able to walk more than a mile a day and stated that she had never felt better.

Fried, in the report of his case, gave a therapy of moderate intensity and at intervals of one week. O'Brien used relatively low intensity in his earlier cases, but in his later cases gave greater intensity and on successive days. Our case received approximately similar intensity and daily applications, but also to a larger total dose. It would appear to be safe to give the larger doses and greater intensity, and possibly obtain more prompt effect. A large series of cases would be required to establish whether this is a fact. The skin of this patient was found not to be hypersensitive to radiation. The history of the development of this method of treatment and a very comprehensive bibliography is to be found in O'Brien's paper in *Radiology*.

Acknowledgment

We wish to thank Dr Clarence C Hare who made the neurological examination and established the diagnosis. We also extend our thanks to Drs Herbert A Cochrane and Joseph H Diamond for permission to report this case.

PROGRESSIVE MUSCULAR DYSTROPHY

A Biochemical Endocrine Study

LOUIS BERMAN, MD, *New York City*
The Neurological Hospital

The pathological physiology and biochemistry of progressive muscular dystrophy still remain to be clearly elucidated. The following studies of certain of the biochemical characteristics of the disease, and the response to endocrine therapy intended to effect these biochemical abnormalities are offered as a more hopeful line of investigation and progress than any that has so far been at hand.

Pathologically not much can be gleaned as to the nature or causation of the disease process. There is an evident degeneration of the striated muscle fibers, and replacement by fat and connective interstitial tissue. The loss of substance and structure with replacement by fat and collagenous tissues are present to a degree proportional to the duration of the disease. Hypertrophied and atrophied fibers occur in the same section of the muscle, and the characteristic signs of degeneration, distortion, and splitting of the fibers, fraying or vacuolation and loss of distinctness of the striae—all point to a disturbance of the nutrition and chemistry of the muscle cells as the underlying process of the disease. Consequently attention was turned to the study of the metabolism and the regulators of metabolism, the endocrine glands, in these patients.

It was at first thought that the seat of the disease was primarily in the nervous system, but the study of the nervous system has failed to reveal changes comparable in extent or gravity with those in the muscles.

In the studies conducted by the writer, the following metabolic changes have been discovered to be constant characters of the disease.

1 A hypoglycemia more marked than that which occurs in any other form of myoneural pathology.

2 A disturbance of the blood sugar tolerance.

3 A hypocholesteremia.

4 A creatinuria, with a disturbance of creatine tolerance.

1 The hypoglycemia associated with the condition adds to the muscular weakness, if not being actually a primary case of it. Actively contracting muscle consumes blood glucose to the possible extent of six times as much as the resting muscle. Long ago Weiland¹ showed that in human beings severe muscular exertion would reduce the general blood glucose from 0.09 to 0.065 gms per 100 c.c. As the blood sugar diminishes, the muscular power of contraction decreases, but may be restored by the injection of sugar. The diminution of blood sugar and the enfeeblement resulting may be demonstrated definitely in the case of the perfused heart. The ability of the heart to contract decreases as the sugar of the perfusing solution is diminished. So introduction of glucose may start such a heart muscle preparation beating after it has stopped contracting. Normally the concentration of blood sugar is stubbornly maintained even through a prolonged period of starvation, the glucose being replenished from the glycogen stores of the tissues. The liver, of course, is the great locus of glycogen storage and the center of the glycogenesis-glycogenolysis mechanism. The blood sugar content and reactions can be affected by changes in the liver, the pancreas, the adrenals, the thyroid, and the parathyroid and the pituitary. In fact there is no better example of how the endocrine glands act as an interlocking directorate over the various metabolic processes than in this of the regulation of the sugar content of the blood and tissues. If the liver becomes badly damaged, its ability to synthesize and store glycogen may be impaired, and hypoglycemia results. Blood sugar may be decreased when the adrenals are removed, and increased by the injection of cortin or adrenalin or both.

After hypophysectomy, hypoglycemia results which may be corrected by the administration of the blood sugar raising principle of the anterior pituitary.

Her chief complaints included weakness, difficulty in walking, and pain in back. Patient has become progressively weaker in the past six months. Her grip has become progressively weaker in the past six months. Her grip has become so bad that objects fall out of her hands. Four months ago, began to experience difficulty in walking. She attributed this to her weakened condition. Her difficulty in locomotion has become rapidly worse so that now she is forced to spend most of her time in bed. Her legs are stiff when she attempts to walk and she has trouble in keeping her equilibrium. Patient has complained of pain in the small of her back for the past two years. Pain at times is shooting or boring in character and is ameliorated by exercise. Her teeth had been previously extracted in an attempt to remove focal infection and thereby to relieve her back pain. Dyspnea and palpitation on exertion. No ankle edema. Dysuria in last four months.

Her past history was irrelevant. Had eight children. No miscarriages.

Physical examination revealed a well-nourished, colored female, weighing 134 lbs. Heart and lungs negative, pupils round, equal, react to light and accommodation, no nystagmus, extraocular movements, no facial weakness, tongue in midline, no rigidity of neck, abdominal reflexes absent, paresis of both hands, atrophy of interossei muscles, temperature and pain sensation increased in fingers, hands and forearms, more so on the left side, pectoral, triceps, biceps, ulnar, and radial periosteal reflexes bilaterally hyperactive and Hoffman sign positive, all reflexes of lower extremities are exaggerated, Babinski positive, Romberg negative, muscle, tendon and joint sense intact, more sensitive to pain on the right side, temperature sensation markedly diminished in the entire left calf, vibration decreased, indefinite area of hyperesthesia in supraspinatus areas beginning at level of second thoracic spine.

Laboratory

Hgb seventy-four per cent, erythrocytes 4,270,000, leukocytes 4,750, polys seventy-three per cent, lymphocytes, thirty-two per cent, monocytes four per cent, eosinophiles one per cent.

Urine albumin 2+, granular casts. Blood Wassermann 1+, repeated twice, negative.

colloidal gold curve negative, sugar 0.43 mgm.

X-ray of cervical, dorsal, and lumbar vertebrae negative.

Treatment

Patient received thirteen applications of 150 r each within a period of sixteen days. They were given to alternate sides of the posterior cervicodorsal spine, the beam being angulated toward the midline. Each portal was eight X thirty cm. The other factors were 200 K.V., filter 0.5 mm. Cu. and 1.0 mm Al, FSD fifty cm.

Improvement began to appear after the first week of treatment. On May 6, 1936 patient was able to walk about without much difficulty although gait was still somewhat spastic. All reflexes were less hyperactive. Babinski reflex was now absent. Superficial abdominal reflex present. Paresis of hands had disappeared and patient was able to take care of her household duties. Sensation of pain had returned, temperature not completely, especially in fingers and left calf. On July 26, patient was again seen. She was able to walk more than a mile a day and stated that she had never felt better.

Fried, in the report of his case, gave a therapy of moderate intensity and at intervals of one week. O'Brien used relatively low intensity in his earlier cases, but in his later cases gave greater intensity and on successive days. Our case received approximately similar intensity and daily applications, but also to a larger total dose. It would appear to be safe to give the larger doses and greater intensity, and possibly obtain more prompt effect. A large series of cases would be required to establish whether this is a fact. The skin of this patient was found not to be hypersensitive to radiation. The history of the development of this method of treatment and a very comprehensive bibliography is to be found in O'Brien's paper in *Radiology*.

Acknowledgment

We wish to thank Dr Clarence C. Hare who made the neurological examination and established the diagnosis. We also extend our thanks to Drs Herbert A. Cochrane and Joseph H. Diamond for permission to report this case.

July 1, 1937]

of interlocking chemical reactions by which the energy for the contraction of the muscle is liberated and the recovery from fatigue is facilitated. To these four might be added cholesterol, although its precise function in the chain of reactions is not known, for Berman has reported that certain cases of extreme muscular fatigability and wasting may be relieved by the innunction of irradiated lanolin, and he has called the condition *asthenia cholesteropriva*. These cases show a markedly lowered blood cholesterol without a hypoglycemia comparable to that occurring in progressive muscular dystrophy.

The adrenal glands, and more particularly the cortex, may be related to these disturbances of muscle chemistry in progressive muscular dystrophy. As mentioned, one of the characteristic accompaniments of adrenal insufficiency, experimental and clinical, is the lowered blood sugar. Recently it has been shown that the carbohydrate chemistry of muscle is disturbed after adrenalectomy. Moreover, the hypoglycemia of Addison's disease is accompanied by a hypocholesteremia. Though a primary function of the cortex seems to be a regulation of the sodium potassium balance in the blood and tissues, it does seem to have a definite relation to the carbohydrate metabolism of muscle dystrophy.

The relation of the phosphocreatine phase of the problem to the creatinuria has aroused the greatest interest. On the basis of the relation of creatine to the simplest of the amino-acids, glycine, which is amino-acetic acid, a relationship to creatine metabolism has been postulated. Very few studies have been made of the relation of the known hormones to the muscle phosphocreatine. Imrie² and his collaborators have studied the relation of the parathyroid glands to phosphocreatine and came to the conclusion that in parathyroidectomized cats, the concentration of creatine phosphate in the muscles is lower than in the normals. The administration of parathyroid extract to such animals results in a restoration of the phosphocreatine content and at a rate similar to that of the normal.

An attempt to influence the carbohydrate metabolism of the muscle in the

progressive muscular dystrophy was first made by Kure and Okimaka.⁴ They used adrenalin combined with pilocarpine upon the theory that the disease is due to disturbance of the autonomic nerve supply of the muscle. They reported favorable results in certain cases. Hough⁵ repeated their work and asserted that in four out of sixteen cases thus tested, there was marked improvement. However, no definitely objective criteria was employed to check the reports of subjective improvement in these cases.

A number of clinicians have considered the endocrine possibilities of etiology and therapeutic attack upon the problem of progressive muscular dystrophy. Endocrine stigmata have been frequently observed such as dryness and pigmentation of the skin, brittleness of the hair and nails, hypertrichosis or deficiency of hair development, disproportion of the skeletal relations, and so on. That muscular dystrophies have been observed in association with dwarfism, exophthalmic goiter, cryptorchidism, eunuchoidism as well as acromegaly, has also been considered additional evidence. However, it is also evident that it is not a monoglandular disease, but rather would have to be classified as a disease of disturbed endocrine function of at least two or more glands. Certain cases have been reported in patients with hyperthyroidism (Boveri, Von Werdt⁶). Richardson and Shorr⁷ have reported that there is decreased creatine tolerance in hyperthyroidism associated with creatinuria, which may be corrected with Lugol's solution. But the creatinuria, and decreased creatine tolerance of progressive muscular dystrophy are not affected by Lugol's solution. Involvement of the pituitary has been considered in certain cases presenting the bony changes of acromegaly. And other cases have been reported to show early calcification of the pineal and it has been claimed that the feeling of pineal produces improvement.

In 1925, I was studying the relation of the parathyroid glands to intermediary metabolism and I was struck with the prompt appearance of creatinuria in parathyroidectomized animals and its equally prompt alleviation by the administration of active parathyroid extract. At about this time, two children of the

Post-pituitary extract will produce hyperglycemia. Even the parathyroid glands are implicated in sugar metabolism, for after parathyroidectomy, the injection of adrenalin no longer causes enough of a hyperglycemia to produce glycosuria. And of course the pancreas through insulin exercises a fundamental regulating influence on the level of the blood sugar. The lowest degrees of hypoglycemia, however, are produced by adrenalectomy experimentally, and occur in Addison's disease, clinically. In Addison's disease, there is a fair degree of correlation between the degree of muscular asthenia and the hypoglycemia and in cases responding to treatment a definite parallelism has been found between the increase in blood sugar and the decrease of asthenia. That is what directed my attention to a study of the clinical and therapeutic possibilities in the employment of adrenocortical extract (cortin) in progressive muscular dystrophy, for in this disease there is a hypoglycemia of twenty to thirty-five per cent below the normal basic fasting blood sugar levels, and there is, moreover, a parallelism between the degree of muscular weakness and the amount of lowering of the blood sugar. This was first reported by McCrudden and Sargent² in 1916. They showed, too, that this hypoglycemia is not due to the wasting of the muscles nor to a lowered need of glucose by the atrophied muscles, for they found no such hypoglycemia in individuals with progressive chronic arthritis in whom rapid and marked atrophy of the muscles is striking. Nor did they find it in progressive muscular atrophy, nor in various other causes of secondary muscular wasting.

2 A change in blood sugar tolerance occurs in progressive muscular dystrophy, which is an increase in tolerance. After the administration of the glucose, the initial rise is abnormally large in relation to the fasting figure and there is a delay in the removal of the sugar from the blood (four to five hours instead of two for return to initial figure), and in a number of the cases the sugar spills over into the urine and transient glycosuria appears. This was first reported by Janney, Goodhart, and Isaacson in 1918.

3 Hypocholesteremia has been found to be the rule in progressive muscular dystrophy, accompanying the hypoglycemia. In general there is no necessary parallelism between the sugar and cholesterol content of the blood. There is one clinical condition in which there is a definite parallelism between the blood sugar and blood cholesterol and muscle activity and that is again Addison's disease, in which the hypoglycemia, hypocholesteremia and muscular asthenia run together, become worse together and improve together under the influence of adrenocortical extract or cortin.

4 Creatinuria is a definite accompaniment of true instances of progressive muscular dystrophy, large quantities of creatine being constantly found in the urine. Such creatinuria is entirely abnormal for adults, although normal for children and, during menstruation, in women. A relation between creatinuria and an abnormality of creatine metabolism was early noted. Creatinuria has been found by numerous observers in many diseases affecting the muscular system. There is also a relation between creatinuria and the amount of protein ingested. But with the protein kept fairly constant, creatinuria will appear where there is injury of some sort to the carbohydrate metabolic mechanism. Hydrazine and phloridzin poisoning, resulting in hypoglycemia, will, in dogs and rabbits, be followed by creatinuria. There is also a tendency to a reduction of the urinary creatine.

A disturbance of the urinary creatine creatinine ratio may be found in all conditions involving muscular wasting or dysfunction, being an indicator simply of the muscular efficiency of the individual as Shaffer first pointed out. The true creatinurias are accompanied by the decrease of creatine tolerance. While the normal individual has a definite capacity to store ingested creatine, the dystrophic will promptly and largely excrete ingested creatine and this may be made the basis of a definite creatine tolerance test.

These chemical disturbances in progressive muscular dystrophy must be related to the known facts concerning muscle chemistry. It is known that four sets of substances are involved in a series

test in the normal will show about the same ratio. In the pathological the creatine tolerance is disturbed in that the ratio falls even lower with the administration of creatine. The following tables show how in three cases there was a marked rise in the ratio, on a regular meatless diet and when creatine was additionally administered in the tolerance test. This demonstrates that accompanying the clinical improvement there was a marked change for the better in the chemical metabolism of the muscle cells, probably due to better phosphocreatine synthesis (parathyroid) and coordination with the sugar processes of muscle contraction (adrenal cortex).

Thus at the end of about four to six months of treatment the ability to retain creatine was improved by about fifty per cent. Accompanying this increased creatine tolerance, was a definite clinical change for the better, of which the patients themselves were quite conscious, and much greater than that obtained under other forms of treatment.

Summary

Upon the theory that the hormones

most definitely involved in the disturbances of sugar and phosphocreatine metabolism in progressive muscular dystrophy were those of the parathyroid and adrenal cortex, these were administered to twenty-two patients in various stages and ages of the disease. Accompanying marked clinical improvement in fifteen out of twenty-two, there was a rise in the blood sugar, and blood cholesterol, and a normalization of the blood sugar tolerance curve together with a reduction in creatinuria and an increased creatine tolerance signifying an increased ability

same family suffering from progressive muscular dystrophy came under my supervision, and among other things parathyroid extract was given hypodermically. Some diminution of the creatinuria was observed and some improvement of the general condition. However, there was no effect upon the blood sugar or the sugar tolerance curve or the fatigability or the size of the muscles. In 1927, I began using an adrenocortical extract with the hope of influencing the blood sugar and thus perhaps the utilization of the sugar by the muscle. After a period of treatment there was a definite rise in the blood sugar, and some effect, by no means as marked as the effect of parathyroid extract upon the creatinuria. It was decided to employ the combined effect of both parathyroid extract and adreno-cortical extract. I have thus treated twenty-two individuals—six children, ten adult males, and six adult females. Hypodermic injections of the standardized extracts were given regularly three times a week over a prolonged period of time. Of the twenty-two, ten were relatively in the beginning of their disease, with symptoms of two years or less duration. This group responded extremely favorable to the combined therapy. In a second group of five, with duration of two to five years, there was a markedly beneficial effect in two, with apparent arrest of the disease, and in the third group of seven, with history of more than five years duration, there was fluctuating improvement in some, with unmistakable gain in strength and decrease of fatigability. In two of these in whom the disease had hitherto been progressive, an arrest of the further progress of it seemed to have been produced.

Associated with the subjective and clinical improvement and apparent arrest of the disease with apparent restoration of such function, in fifteen out of the twenty-two here reported were marked and definite changes in the biochemical and metabolic manifestations of the disease. There was a rise in the blood sugar of about 25 to 40 per cent, the blood sugar tolerance curves changed to a more normal type of curve and there was also a definite rise in the cholesterol content of the blood in those in whom

it was lowered. In addition, there was a marked reduction in the creatinuria, with a reversal of the creatine-creatinine ratio. Creatine tolerance tests carried out in the last four years have also shown a decided increase in the ability to hold ingested creatine and to transform it into creatinine.

These objective metabolic-biochemical changes accompanying the clinical improvement in the early and relatively not so far advanced types of progressive muscular dystrophy taken together with clinical improvement exhibited in muscular ability to perform coordinated habit movements, increase in strength and size of muscles, and increase in resistance to fatigue and ability to recover from fatigue would seem to indicate a real influence of the combined parathyroid-adreno-cortical extract treatment upon the cause and the course of the disease. Neither parathyroid alone, nor adrenal-cortical extract alone produce as good effects as those obtained when both are administered together. Isolated case reports have appeared in the literature regarding the effect of adrenal-cortical extract alone or parathyroid alone, but there have been no studies of the effect of either alone or combined upon the metabolic and biochemical phenomena. The striking changes observed with the combined extracts warrants further use of them and continued exploration of their therapeutic possibilities. Where there is marked atrophy and loss of muscle substance relatively little can be expected. But in the earlier and more florid stages of the diseases much may be accomplished by this therapy.

The effects upon the creatine tolerance in these treated cases is quite striking. The results in three may be cited as illustrative of the general trend in those individuals who have improved under the treatment. The normal creatine-creatinine ratio in a twenty-four specimen of urine is ten. That is, the amount of creatinine excreted in that time is about ten times that of creatine. In disturbance of muscle chemistry associated with abnormality in the phosphocreatine metabolism, there is a fall in the ratio because an increased amount of creatine is lost through the kidneys. A creatine tolerance

ESOPHAGEAL OBSTRUCTION

Seventy-eight Hospital Cases

EINAR A. SUNDE, M D, F A C S, *Brooklyn*

The following cases are reported as being of interest to the profession because they show the incidence and variety of esophageal disease as it occurs in an average general hospital rather than as it occurs in special endoscopic clinics.

The average yearly admissions at the Methodist Episcopal Hospital, exclusive of the obstetric admissions, are about six thousand. The period covered is from 1921 to 1936. Several cases of pharyngeal carcinoma producing dysphagia have been omitted as not being strictly esophageal cases. Only cases seen by the endoscopic service are considered, and as there are undoubtedly other cases the actual figure may be higher. Considering this series alone, the incidence is one case to 1154 admissions.

Jackson lists twenty-nine conditions involving the esophagus which cause dysphagia, some of which are simple to recognize, while others may require the cooperation of internist, neurologist, radiologist, and endoscopist to reach a diagnosis.

This series of seventy-eight cases of dysphagia due to esophageal disease falls into eight groups, in order of frequency as follows:

Carcinoma	34
Foreign body	29
Cardiospasm	6
Diverticulum	3
Congenital stenosis	2
Acquired stenosis	2
Peptic ulcer of the cardia	1
Acute esophagitis	1

Due to its anatomic position, the esophagus cannot be examined by ordinary means, except possibly in the cervical portion, where palpation may be employed. Previous to the use of x-ray and the esophagoscope, examination was confined to the use of the bougie passed

blindly, a procedure abandoned today as dangerous to life. At present, x-ray examination with contrast media, and esophagoscopy offer a ready means of diagnosis, and every patient complaining of dysphagia should have the benefit of both procedures.

Esophagoscopy carries with it a certain risk unless skillfully done. In this series, 213 esophagoscopies were done with no fatalities due to the examination itself.

The only contraindication to esophagoscopy is the presence of an aortic aneurysm.

Foreign body. The twenty-nine foreign body cases in this series may be discussed briefly. The chief point to remember is that a negative x-ray means nothing. Very few of our cases were diagnosed by x-ray. In fact, with a definite history of swallowing a foreign body, and with the patient in obvious discomfort, x-ray may be dispensed with and immediate esophagoscopy done. Ideally, of course, an x-ray should be obtained in every case. Sudden dysphagia, with pain or discomfort, usually occurring during a meal, is enough to warrant a suspicion of foreign body. When in doubt, esophagoscopy should be done.

Of these twenty-nine cases, the foreign body was found and removed in twenty. In three cases, after temporary lodgement, the invader passed into the stomach spontaneously. In five, nothing was found. One case, a partial denture lodged in the esophageal wall, was sent to the Jackson clinic where it was removed by using a special cutter to break up the denture.

Cardiospasm. We have had six cases of so-called cardiospasm (a misnomer, for the reason that there is no demonstrable muscular sphincter at the cardiac orifice).

Read before the Quarterly Staff Conference of the Methodist Episcopal Hospital, November 18, 1936

of the muscles to handle creatine and apparently as a result of the treatment. These observations, correlated with recent findings concerning the relation of the parathyroids to phosphocreatine metabolism and of the adrenal cortex to sugar metabolism in muscle, would seem to in-

dicate that progressive muscular dystrophy represents a muscular dysplasia occurring upon a basis of an endocrine dyscrasia centering around a deficiency or imbalance of the parathyroid and adrenal glands

WITHOUT GLOVES

The outspoken, vigorous English of our Illinois contemporary never leaves any doubt about where the editor stands. While other medical editors around the land are opposing state medicine firmly, perhaps, but more restrainedly, the *Illinois Medical Journal* speaks its mind thus:

The panel doctor finds himself a physician on the ten cent store idea. Austria, England, France and Germany reverberate to the same wail. Nickle and dime stores may flaunt their wares on the boulevards. Will American citizens have such service in their clinics, their hospitals, or their family sick-rooms?

Justice Oliver Wendell Holmes said "It has long been recognized that legislation is just as likely to follow public emotion as to be guided by scientific knowledge." Oliver was right! But in the case of the

Social Security Act legislation would seem to have followed the public destroyer, and the communist at the gate. If the Puritan ancestors of the late Justice were on the job today it is likely that scientific knowledge of the fowling-piece and powder horn would clean out a few of the warrens of Washington where bureaucracy breeds, communism concentrates, and the Constitution is regarded as lightly as last year's song-and-dance act in the vaudeville show of nations.

What has become of the Declaration of Independence? Where is the Constitution of the United States about to land? According to the present legislative tendency socialistic powers and bureaucratic ideas this sacred document will soon rest in the national garbage barrel.

x-ray series proved to be negative. Esophagoscopy showed the presence of a peptic ulcer of the cardia with moderate infiltration. No malignancy was present. She improved under medical treatment.

Diverticulum of the esophagus, or more properly, of the hypopharynx, occurred in three cases.

The first was a male aged fifty-four who had dysphagia twelve years. Regurgitation occurred, with an eight hour retention. A tumor was felt in the neck, enlarging after eating and diminishing in size in a few hours. X-ray diagnosis of diverticulum was confirmed by endoscopy. A Lahey two-stage operation was done with a successful result. After five years there has been no return of the diverticulum.

The second case, a male aged sixty, had a cough for one and a half years, dysphagia five years. X-ray and esophagoscopy showed a diverticulum. This patient was referred to Lahey at Boston, who operated on him with a successful result.

The third case, a male aged fifty-two had regurgitation one year. X-ray showed a diverticulum the size of a hen's egg. Esophagoscopy confirmed the diagnosis and Lahey operation was done. The patient died following the first stage, from mediastinitis due to accidental perforation of the neck at the sac at operation.

Carcinoma of the esophagus—our largest group—occurred in thirty-four cases. Jackson states that seventy per cent of esophageal stenosis in adults is due to malignancy. The average patient ignores symptoms until after solid food regurgitates, which may occur comparatively early. The duration of symptoms in this series is as follows:

Three cases	one year
One	ten months
Two	six months
Four	five months
Three	four months
Four	three months
Five	two months
Six	one month
Six	not stated in history

Thus it may be seen here that eighteen of thirty-four cases sought relief four months or less after the onset of dysphagia. Unfortunately by the time symptoms occur and the patient seeks relief, the malignancy is well-established and treatment can only be palliative.

The history, familiar to all of us, is one of painless dysphagia, followed by regurgitation. Usually no blood is seen in the regurgitated material. Loss of weight is marked and very rapid.

X-ray findings include (1) Obstruction to contrast media at any level. (2) Irregular lumen. (3) Slight or no dilatation above point of obstruction. The walls are more or less fixed.

Endoscopic findings The lumen is obstructed by either an indurated annular stenosis, an ulcer, or a fungating growth which bleeds easily on touch. The diagnosis is made on biopsy. Lues and tuberculosis must be excluded.

Location of growth Upper third of esophagus—thirteen cases, middle third—ten, lower third—ten of which five were at the cardia, one case refused examination and the growth was not located definitely.

Sex Male twenty-six, female eight.

Age Average sixty, youngest thirty-nine, oldest eighty.

Gastrostomy was done in eleven cases, five of whom died in the hospital, and six left improved as to their general condition.

Ten of the thirty-four died in the hospital, five of inanition, two of terminal pneumonia, and one each of hemorrhage, spontaneous perforation (mediastinitis), and cardiac failure.

Twenty-one cases left the hospital unimproved, the majority of whom were referred elsewhere for radiation therapy.

Three cases were discharged improved, two of whom received radon seed implants with slight temporary improvement. The other case, the most recent of our series, is the only one that has occurred since the installation of a new radiation therapy unit, and this case gives us hope of at least better palliative results than we have previously obtained.

This case was a male, age fifty-eight, who had dysphagia for two months. X-ray and esophagoscopy diagnosis was carcinoma of the cardia. Biopsy showed a grade two adenocarcinoma. X-ray therapy was begun, had to be interrupted by a gastrostomy and was resumed again. He received a total of 4000 r units over two ports. Esophagoscopy, two days after finishing this course of treatment, showed a

Jackson prefers to call it "diaphragmatic pinchcock stenosis." The abnormal closure of the esophagus occurs at the diaphragmatic level, an inch or more above the true cardia, and is caused by muscle bands springing from the crura of the diaphragm surrounding the esophagus at the under surface of the hiatus.

There is also a normal twisting or kinking of the terminal portion of the esophagus which aids in the closure. Mosher has demonstrated this on cadaver specimens and has shown that the left lobe of the liver impinges on the esophagus and may produce blockage by pinching the esophageal wall against the left crus of the diaphragm.

Normally also, the left lung tip presses on the esophagus and pinches it off during inspiration. This may be seen under the fluoroscope.

The etiology of cardiospasm is still obscure and is probably linked in some way with the nerve supply to the esophagus and the diaphragm.

These cases complain chiefly of regurgitation and may often mistake it for vomiting, particularly if a large dilatation is present. The fluoroscopic picture is typical. The contrast media descends to the level of the diaphragm without difficulty, but is stopped at that point. The esophagus is dilated above this point to a greater or less degree, the walls are smooth, and the contrast media presents a pyriform shape, tapering to a point at the diaphragm. Some of the barium may enter the stomach as efforts to swallow are continued. The greater amount is retained in the esophagus for a time and slowly trickles through into the stomach. If the closure is tight, the contents are retained part of the day and is then regurgitated later (twenty hours in one of our cases).

On examination, the esophagus is found dilated, and the walls smooth. A chronic esophagitis is present, the result of food stagnation. At the bottom, one finds the opening more or less tightly closed. Bougies are passed carefully and this procedure is repeated weekly until the lumen allows the passage of the tube itself. Permanent relief is usually obtained. Some cases recur, when the process must be repeated.

Of six cases, four were female. The

average age was thirty-eight. Five cases left the hospital improved after one or more dilatations. One case had a gastrostomy done and a finger dilatation from below through the stomach. The patient was discharged improved.

Congenital stenosis may be one of many varieties. If any lumen at all is left, bouginage is invariably successful.

Of two cases, one was a fourteen month old infant with a web just below the cricopharyngeus muscle. The web was divided with subsequent improvement. She returned at the age of two years with further obstruction. Dilatation was done with improvement.

The second case was that of a four year old boy with a history of dysphagia since infancy. A stenosis was found in the middle third of the esophagus. He has had about thirty dilatations. He is now ten years old and swallows normally. At first this was thought to be a lye stricture, but no history of a lye burn could be obtained, there were no scars in the esophagus, and he was finally classed as a congenital case.

Acquired cicatricial stenosis two cases, both in the middle third, were treated successfully with dilatation.

Acute esophagitis, usually caused by trauma or a lye burn, occurred in one case following appendicitis with general peritonitis.

A male, aged thirty-eight, began to have difficulty in swallowing two weeks after his discharge from the hospital following an appendectomy with drainage. He lost fifteen pounds. On admission he had some cough and considerable soreness on swallowing. During his first week in the hospital he ran a low grade temperature. X-ray showed a complete obstruction in the middle third of the esophagus. Esophagoscopy discovered an acute esophagitis with a marked narrowing of the lumen. Exudate on the wall of the esophagus showed pus cells, with pneumococci and streptococci predominating organisms. Improvement occurred with rest and dilatation. Complete recovery took four months.

Peptic ulcer of the cardia (one case only) occurred in a female, aged sixty-two, who was admitted exsanguinated from an occult hemorrhage. It was thought she had a gastric ulcer or malignancy. After transfusion and improvement in her condition, a gastrointestinal

not only because the child was a female, which is usually an important factor, but also because he was busy in his downtown office and was less at home than his wife. On such occasions it is ordinarily the mothers who bear the brunt of the burden. They feed and bathe, dress and put to bed the children, clean the teeth, nose and ears and wash the hair. They are the ones to go out with them every day, to hurry and admonish them. The father's walk with the child, on Sundays, is a holiday full of serenity. This father was "a good father," he came home early evenings and took part in some of the ministrations connected with upbringing. *Inde irae*, as Juvenal would say. That is why he did not escape his child's enmity entirely.

The grandmother also came to my office and acted as informant. She had arrived from Germany only ten years before and scattered words from her own language into her English. She denounced the parents frankly. They had spoiled the child, *das Kind*, and now they reaped what they had sown. The girl was not born bad. But now she was terrible. "Just as you cannot stop the wind, so you cannot check this *Kind*," she unconsciously rhymed.

Patient was fifty-three inches tall and weighed only 50 lb., which amounted to fifteen or more lb. underweight. The physical examination was negative. She was dark complexioned like her father, but otherwise she did not resemble him. She was extremely vivid, while he, when not aroused, was slow and deliberate and, according to the old lady, his mother, had apparently been so in childhood.

The child's face, framed in by a shock of jet black hair, her piercing glances from the shining, always moving and searching eyes, were disconcerting and discouraging.

Forever teasing and defiant, she seemed unconquerable.

When I began to talk to her, she turned her back to me, went to a corner of the room and covered her eyes with her hands.

I said "Oh, I like to talk to people without seeing them. I have friends whom I have never seen."

She became immediately interested and, forgetting her evident resolution not to speak to me, she turned quickly around and asked "How can you do it?"

"We only correspond," I answered. "By mail, you know. I get the best there is in them and I am sure not to disappoint them."

"What do you mean?"

"I mean they cannot see my weak points in my letters, although truthful, I am like

somebody dressed up in his Sunday best clothes."

But after a while she put her tongue out in my direction and made a wry grimace.

"I too can make faces," I said, "but I am making them in a funnier way when I am alone, in public I am ashamed."

"Let's see," she urged.

And I twisted my features as grotesquely as I could, which made her laugh.

From then on we were friends and the astonished parents admitted that they had never seen her so affable and cordial, specially with a stranger.

When I mentioned her slimness and gave her reasons why it was necessary for her to gain weight, she became serious and was willing to be examined physically. But she said she wouldn't want to be like me and I conceded that I was a little too stout. I showed her, however, that I could run and jump better than her. Try as she may, she remained behind in every contest, which enhanced her respect for me. She turned to her parents and said "He is like Foxy Grandpa of the funny page."

We spoke about the pictures on my wall and I made up stories about their contents as we went from one to the other. She said she could also paint and she drew a landscape for me—not bad. We conversed about many things and she was never aware that I was testing her intelligence and gauging her mental possibilities in an unconventional manner. Mentally she was normal if not above.

The parents had been silent witnesses. Before going home they both expressed the hope that from then on Louise would behave. But I told them they were mistaken and asked them to call without the child.

I had to lecture them, to point out their errors in upbringing from the moment the child was born and to plan for the future.

When I saw the little girl again many of her difficulties were still present. Several talks on the one side with her and on the other side with her parents were necessary. Serious blunders made by them, old faults, oversights, like creases in worn garments, persisted and continued for a long time and hindered the improvement. Nor did the child's attitude to them change overnight. Her misbehavior recurred again and again but her periods of adjustment increased.

While I do not think that a child who has been sinned against so much up to the age of nine or ten and who has adopted a distorted point of view of her surrounding world can ever correct it entirely, her conduct became and remained quite tolerable.

complete disappearance of the growth which had previously filled the lumen with a fungating mass. At this time, 100 mgm of radium, screened with $1\frac{1}{2}$ mm of platinum was placed in the cardia and held there for eighteen hours (1800 mgm hours). Following this treatment, he began to improve and after a time could eat solid food. Four months after treatment he died suddenly of heat stroke after having eaten a full meal. The diagnosis of heat-stroke was made by his family doctor who was fully aware of his previous condition.

Treatment of these cases is well-illustrated by the above case report.

Bouginae for temporary increase of lumen is contraindicated owing to the risk of perforation and possibility of spreading the growth. Intubation may delay gastrectomy but will not obviate its eventual performance. Gastrectomy should be done earlier in cases showing solid food regurgitation, thus preventing starvation acidosis.

Surgery has not yet reached the point where it can successfully attack this condition and so our main reliance must at present be placed on radiation therapy.

627 SECOND ST

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D, Dr P H, New York City

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polytechnic Medical School and Hospital. The descriptions are not complete clinical studies, but will occurrent situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Father and Daughter

Man, sixty "Nervous Breakdown" since his only daughter married and left the house, a year ago.

Daughter is happy.

Patient otherwise healthy. Strong, tall, well-built.

"Melancholy," unable to continue his occupation, which is that of a bookkeeper in a large concern. Coming with his family physician, who has vainly tried all sorts of methods.

Questioning gradually revealed that he suffered from a subconscious—perhaps conscious—exaggerated love for his daughter which is a concomitant of and a compensation for his eternal fights with his wife and

hatred for the latter. He managed to find employment for the girl in the office where he himself was working and where he kept her as long as he could, so he might be in her proximity. But her marriage, although he did his best toward its success, proved to be a shock to him when accomplished.

Several talks. Carefully explained the situation to him. Shown how necessary it was for him to overcome his sentiments toward his daughter and that the pretexts for his bad feelings to his wife were founded on futile and foolish details and imaginary wrongs.

Improvement. Returned to work and became cheerful.

The Problem Child

Louise, nine, was a *behavior problem*.

She was restless, unadjusted, rebellious. She disliked school, had a bad temper, could not get along with other children. She was cruel and hit anybody who came near her, often even her mother. Her parents, both professional persons and above the average in intelligence, had lost their influence with this their only child and, what was worse, were also losing their patience. They too had frequent uncontrolled outbursts of anger which the child imitated, a fact that put them into a worse rage. Then they blamed each other and quarreled among themselves. Sometimes the old grandma

who was living with them mixed in and the uproar grew and grew until there was pandemonium.

The child ate badly and her food preferences were capricious and very limited. Almost from infancy, that is from the moment she understood that the mother was very keen on having her eat, she was opposed to eating. As it always happens in these cases the child, in her fight against the maternal tendency to overfeeding, had learned very early her opponent's weak point and had taken advantage of it.

The child's hatred for the father was less pronounced than that for the mother,

difficult task. Medical care, scientific research, and professional education are all functions of the modern medical institution. To be discharged properly, they demand integration of the hospital with other social and philanthropic movements, sound business procedure on the part of executives, familiarity with medical aims and methods, and a sympathetic understanding of the problems and needs of the professions associated in health services.

While it is possible for an intelligent, experienced layman to discharge the manifold duties of hospital administrator with distinction, there is no doubt that a medical education provides the most appropriate background for this work. It is not, however, enough. On it must be superimposed a thorough understanding of the numerous extra-medical problems of institutional management. Executive talents must be consciously developed.

The Hospital for Joint Diseases in New York City is conducting an interesting experience in training for hospital administration. It has established a three-year residency in this field, during which the successful candidate acquires practical experience in every phase of institutional management. He studies and supervises admitting procedures, the organization of the house staff, emergency and ambulance service, the house-keeping, engineering and business divisions, community relations—in short, everything pertaining to the planning, construction, and operation of a modern medical institution.

With hospitals assuming an increasingly important role in medical service, the quality of hospital administration also grows in importance. This work should be considered a career in itself by those who enter upon it, not a stop-gap in the absence of other employment.

To this end, accredited training facilities are essential. If the experiment of the Hospital for Joint Diseases succeeds, it will point the way for the development

of a group of experienced hospital administrators within the profession.

Choosing the Medical Student

Between now and the commencement of the Fall term, the personnel of all medical colleges is confronted with the difficult problem of selecting a class of students who are fitted to the study of medicine. The task is no easy one, and the responsibility is not light, for upon these schools the American people are dependent for their supply of future medical care.

A far greater number would become physicians than either the physical capacity of our schools could train or that the community can utilize. Consequently a system of selection must of necessity be enforced lest we be overrun by a vast number of misfits. That no system of selection is perfect goes without question and in some instances, unintentional injustices do occur. It is a hard problem to determine beforehand which one will and which one will not make a doctor who, besides being a source of pride to his profession, will adequately and honestly serve the public. One has but to read the minutes of the thirty-third Annual Congress on Medical Education and Licensure to appreciate how much thought is being given to this phase of medical education. Scholastic standing, while important is by far the least important, being overshadowed by personal qualities such as honesty, faithfulness in the performance of work, and the total lack of demoralizing traits.

To those applicants who fail to make the grade we extend no sympathy because they later in life will thank the medical schools for having had the foresight of avoiding for *them* an unsuccessful and monotonous career—a career for which they were not suited. To those chosen we recommend a careful and reverent study of the highest traditions of medicine throughout the centuries that they

The A M A Meeting

Physicians who have derived their impressions of the recent A M A meeting from headlines in the lay press are far from an actual picture of what transpired. Organized medicine has not accepted socialization, as so many newspapers appear to believe. On the contrary, it has strengthened the status of private medical practice by bringing it into conformity with the needs and realities of the times.

The proposals made represent no departure from the policies endorsed by the membership at the recent State Meeting. They are in no wise revolutionary, as some journalists like to describe them. The profession has long urged government to acknowledge its responsibility for the health of the indigent and medically indigent. It has repeatedly expressed its desire to cooperate with responsible agencies to the end that suitable health policies be devised and carried out without political interference or control.

The fact that the A M A has declared such views its official policy is no basis for assuming that it has endorsed socialized medicine—unless we consider that we are living in a socialist state because the government supplies the needy with food and shelter and other necessities of life. Physicians consider medical service

one of these necessities—and believe it can best be furnished through the private practitioner, even when governmental aid is necessary to pay the bill.

In taking this stand neither the A M A nor the State Society has abated its opposition to compulsory sickness insurance by one iota. The compelling objections to this system still hold good. That the government realizes their validity, is indicated by the President's request for cooperation "in such methods as you (i.e., the President and the A M A) would jointly find would be to the service of the helpless and the afflicted, within such province as you felt government should undertake."

The popular response to the A M A's declaration of policy and the President's immediate acceptance of its offer of aid imposes an inescapable obligation upon the profession. If the latter ignores this responsibility and settles down into a "do nothing" policy, it cannot complain if more energetic agencies seize the opportunity it ignores.

A Good Apprenticeship

Even in comparatively small hospitals today administration is a complex and

difficult task. Medical care, scientific research, and professional education are all functions of the modern medical institution. To be discharged properly, they demand integration of the hospital with other social and philanthropic movements, sound business procedure on the part of executives, familiarity with medical aims and methods, and a sympathetic understanding of the problems and needs of the professions associated in health services.

While it is possible for an intelligent, experienced layman to discharge the manifold duties of hospital administrator with distinction, there is no doubt that a medical education provides the most appropriate background for this work. It is not, however, enough. On it must be superimposed a thorough understanding of the numerous extra-medical problems of institutional management. Executive talents must be consciously developed.

The Hospital for Joint Diseases in New York City is conducting an interesting experience in training for hospital administration. It has established a three-year residency in this field, during which the successful candidate acquires practical experience in every phase of institutional management. may preserve them in the midst of this rapidly changing social order

The Menace of "Nose Drops"

Since 1925 the profession has become aware of the dangers inherent in the use of oily preparations in the nasal passages. Especially is this true for infants under two years of age. The oil, aspirated into the lungs, produces a low grade pneumonia which most often terminates fatally. Postmortem examination frequently reveals large quantities of oil in the lungs and the tissues show the reactions common to foreign body irritation. Death results from a superimposed infection.

This form of pneumonia, called lipid pneumonia, has been on the increase in recent years due to the extensive advertising of commercial "nose drops." A well-intentioned mother, whose child has a "running nose," repeatedly instills oily drops into the nose in the mistaken belief that they are curative. Medical men know that any medication to the nose in the form of drops is at best a palliative but they are powerless in their attempt to combat the advertising of large patent medicine concerns. The situation has produced a definite health problem. According to Dr. Paul Klemperer, "the condition is now being found with increasing frequency at autopsy. Occurs in adults as well as children. The condition constitutes a public health menace."

The profession feels that an intensified campaign should be instituted by the health authorities to acquaint the public with the truth regarding the use of oily nasal drops. It feels that this problem should be made a part of the Pneumonia Campaign now in progress.

CURRENT COMMENT

"INSTEAD OF THE GOVERNMENT taking charge of directing the doctor as to what is to be done in the matters where his science

is of first application, I want the government to place the doctor in a position where he can direct the government."—Senator Lewis, speaking to the House of Delegates of the A. M. A. on June 10, 1937

ON A QUESTION OF LONG-STANDING we quote two standpoints—an editorial in *The New York Times* of June 4, and an elucidating letter from Dr. Edwin H. Shepard in *The Times* of June 7.

The editor states "In response to the public demand for medical news and in recognition of the part played by the press in combating disease, medical press bureaus have been established. Newspaper men are grateful for their aid in interpreting medicine. But the information supplied about a new discovery is second-hand. There are questions that the reporter would like to ask the discoverer and pictures of the great man that the public would like to see. Woe unto the medico who yields to importunities. He runs the risk of being ejected from medical societies as a publicity seeker. Cruel injustices are sometimes thus perpetrated. The great physicist who grants an interview on his success in driving some new particle of matter of the atom or permits himself to be photographed in his laboratory is certainly no more given to advertising himself than the man who becomes famous through his method of treating pneumonia or schizophrenia. In a democracy where speech is still free the physician is the one scientist who is muzzled."

"The medical bureaus of information have done commendable work in aiding the newspapers to suppress the quacksalvers who seek publicity. Yet only a beginning has been made in bringing about a better understanding between the press and medicine. The next step is to make it possible for men engaged in research to escape ostracism when they satisfy a legitimate demand for first-hand opinions of the kind that the public is entitled to hear."

Dr. Shepard, on the other hand, tells us that "as one who served his first apprenticeship in the newspaper profession and later became a physician, has with years of experience changed his ideas on what may or may not be medical news. Medical news itself is a proper public concern, which is already being recognized in practical co-operation by various county and State medical organizations. News of medical men has a deeper implication. Attractive as it may be to see the features of medical scientists or practitioners in public print, these men themselves know that a free rein in this regard would bring results far too seri-

ous to counterbalance the pleasure of the public in seeing their faces in print.

"I know from experience that almost all the desire and effort for publicity come from the quack and the charlatan. These are the men against whom the ban on publicity is aimed. It is these who have a new 'discovery' to announce always in a field in which there has been limited success by others. It is these who perform a new operation which sounds wonderful but to which no conscientious physician would subject a patient. Without a restraint on these men a vast amount of harm and grief comes to the public.

"The firm adherence of medicine to what it is convinced is right or for the public welfare is an idea which the bulk of social and public workers seem wholly unable to comprehend."

"OF COURSE, THE MONEY TO SUPPORT this plan (compulsory health insurance) comes from pay envelopes. If this goes on, all the worker will get each day is an envelope with a statement inside. He can't eat the statement."—From the *Lewiston (Maine) Journal*, of recent date.

"PHYSICIANS WHO KNOW FROM experience the value of economic preparation, have urged repeatedly that courses in medical economics be included in the medical curriculum.

A course in medical economics will not transport the tyro to Utopia. He will still have to face the lean, early years of practice and experience the painful process of waiting for his office bell to ring.

"At least, however, he will understand what is happening to and about him. The business side of his office will be efficiently run. If he prospers, he will know how to invest his savings wisely and how to secure himself against disability and old age.

"In his relationship with the rest of the profession, too, the influence of economic knowledge will be felt. *He will recognize the importance of strong, militant organization to further the interests of medical men as a whole. He will refuse to be swayed by the winds of spurious social theory* (Italics ours).—H. Sheridan Baketel, writing in the *June Medical Economics*.

SAID GOVERNOR LEHMAN RECENTLY "The State, in medicine and surgery, as well as in almost every other social activity, can do

only a relatively small part of the necessary and essential work. State activity, no matter how well administered, can never successfully take the place of the private practitioner, or the privately endowed institution. Government can never be substituted for the interests of the countless thousands of men and women, both professional and lay, who have given themselves without stint and without thought of self, to the social and technical services which people have come to expect and to demand."

"WHEN IMPATIENT, SELFISH FORCES are colliding violently and impeding the effort of democracy to improve the life of the average man it is like a breath of fresh air in a choking room to have the American Medical Assn., undertake of its own initiative a search for ways to spread the benefits of modern medical science more thoroughly over the population.

"Physicians do not want this problem to be manhandled by politicians, and therefore wisely initiate a movement in the hope that it can be directed by those who know something about the subject."—Raymond Clapper, writing in the *New York World-Telegram*, June 9, 1937.

UNDER STATE MEDICINE *The Sun Dial* thinks "It is even possible that while a doctor will be allowed to say 'Lemme see your tongue,' the actual inspection will have to be done by five Federal commissioners."—From the *New York Sun*, June 12, 1937.

"FOR SEVERAL YEARS PAST the medical profession has been subjected to microscopic study by a great variety of agencies. Some have been looking for evidence to prove that all medical care should be socialized, others have been bent upon showing that socialization would be demoralizing and ruinous. Lately doctors have become highly articulate. Among themselves they have evolved suggestions counter to state medicine.

"There first concern has been to forestall anything like 'socialized medicine,' 'state medicine' or compulsory health insurance, to all of which an overwhelming majority of our doctors are opposed, both as scientists and as good American citizens."—*New York Herald Tribune*, June 13, 1937.

HOUSE OF DELEGATES

MINUTES OF THE ANNUAL MEETING

May 24 and 25, 1937

The 131st Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Chamber of Commerce, Rochester, New York, on Monday, May 24, 1937 at 10 A M

Dr Samuel J Kopetzky, Speaker, Dr James M Flynn, Vice-Speaker, Dr Peter Irving, Secretary, Dr Edward C Podvin, Assistant Secretary

1 Committee on Credentials

THE SPEAKER The Secretary will make a report for the Committee on Credentials

THE SECRETARY There are no disputed delegations, and all those present as delegates are entitled to vote

THE SPEAKER I declare the 131st Session of the House of Delegates open for the transaction of its business

The Secretary called the roll by counties and stated "There is a quorum present."

THE SPEAKER Let us bear in mind those who have passed on since our last session Today we miss Luther A Warren, Daniel S Dougherty, George H Fox, James N Vander-Veer and George A Leitner The House will rise (The House rose for one minute)

2 Approval of the Minutes

On motion, seconded and carried, the reading of the minutes of the last meeting was dispensed with, and the minutes were approved as published in the June 15, 1936 issue of the NEW YORK STATE JOURNAL OF MEDICINE

3 Reference Committees

THE SPEAKER The Secretary will now announce the reference committees

The Secretary read the following Reference Committees

REFERENCE COMMITTEE ON REPORT OF THE PRESIDENT

Warren Wooden, *Chairman*, Monroe
William W Street, Onondaga
Herbert H Bauckus, Erie
Norman S Moore Tompkins
George A Newton, Nassau

REFERENCE COMMITTEE ON REPORTS OF SECRETARY COUNCIL CENSORS AND COUNCILORS

Gny S Carpenter, *Chairman*, Tioga
Coburn A L Campbell, Suffolk
Richard H Sherwood, Niagara
Albert H Gartner, Erie
J Sturdivant Read, Kings

REFERENCE COMMITTEE ON REPORTS OF TREASURER AND TRUSTEES

Terry M Townsend, *Chairman*, New York
William Klein, Bronx
James H Donnelly, Erie
Walter D Ludlum, Kings
Norman S Cooper, Greene

REFERENCE COMMITTEE ON REPORT OF LEGAL COUNSEL

Willard H Veeder, *Chairman*, Monroe
William B D Van Auken, Rensselaer
George S Towne, Saratoga
William C Treder, Schenectady
Floyd J Atwell, Otsego

REFERENCE COMMITTEE ON REPORT OF COMMITTEE ON PUBLIC RELATIONS

Robert Brittain *Chairman*, Delaware
Vincent S Haywood, Bronx
Frederic W Holcomb, Ulster
Robert F Barber, Kings
John J Clemmer, Jr, Albany

REFERENCE COMMITTEE ON REPORT OF COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

Robert Brittain, *Chairman*, Delaware
J J Masterson, Kings
J Stanley Kenney, New York
Anthony J Zaza, Madison
Ross F Wolever, Oswego

REFERENCE COMMITTEE ON REPORT OF COMMITTEE ON LEGISLATION

Horace M Hicks *Chairman*, Montgomery
James H Borrell, Erie
Walter P Anderton, New York
John J Bnettner, Onondaga
Clarence V Costello, Monroe

REFERENCE COMMITTEE ON REPORTS OF COMMITTEES ON SCIENTIFIC WORK AND ARRANGEMENTS

Arthur F Heyl, *Chairman*, Westchester
J Homer Cudmore, New York
Daniel C Munro, Essex
Henry W Miller, Putnam
William Hale, Jr, Oneida

REFERENCE COMMITTEE ON REPORT OF COMMITTEE ON ECONOMICS

James F Rooney, *Chairman*, Albany
Moses H Krakow, Bronx
Harry Aranow, Bronx
David J Kaliski, New York
DeForest W Buckmaster, Chautauqua

REFERENCE COMMITTEE ON REPORT OF COMMITTEE ON TRENDS

Louis H Bauer, *Chairman*, Nassau
Judson M Burt, Livingston
Clarence G Dandler, New York
Chas A Anderson, Kings
Daniel R Reilly, Cortland

REFERENCE COMMITTEE ON REPORT OF WORKMEN'S COMPENSATION PROCEDURE

Joseph C O Gorman, *Chairman*, Erie
Thomas M Brennan, Kings
Julius Ferber, New York
Andrew Sloan, Oneida
William A Peart, Niagara

REFERENCE COMMITTEE ON NEW BUSINESS (A)

Edward R. Cunniffe *Chairman* Bronx
 James Alexander Miller, New York
 Harry D. Mencken Queens
 David W. Beard, Schoharie
 Arthur S. Driscoll, Richmond

REFERENCE COMMITTEE ON NEW BUSINESS (B)

Thomas A. McGoldrick *Chairman* Kings
 Conrad Berens, New York
 C. Knight Deyo, Dutchess
 Reeve B. Howland, Chemung
 Samuel M. Allepton Broome

REFERENCE COMMITTEE ON NEW BUSINESS (C)

B. Wallace Hamilton, *Chairman* New York
 J. Lewis Amster, Bronx
 Harry C. Guess, Erie
 John L. Bauer, Kings
 Edward T. Wentworth, Monroe

REFERENCE COMMITTEE ON NEW BUSINESS (D)

Walter W. Matt, *Chairman* Westchester
 Frederic C. Conway Albany
 Lyman C. Lewis, Alleghany
 Adolph G. DeSancus New York
 James M. Dobbins, Queens

CREDENTIALS

Peter Irving, *Chairman*, New York
 Edward C. Podvin Bronx

4 Address of the President

THE SPEAKER The President has a supplementary report.

DR. WINSLOW This occasion furnishes me an opportunity to submit to you the good wishes of the Medical Society of the County of Monroe.

You may recall that at the beginning of my administration we emphasized four points which we thought necessary to try to accomplish during the past year. They were as follows:

1 To improve the relationship which exists between the everyday practicing physician and members, officers and committees of the Society.

2 To try to improve the efficiency of the Executive Committee.

3 To thoroughly revise the business methods of the Society.

4 To try to improve the relationship which exists between the doctor and the hospital.

Taking this up, point by point, during the last year the officers of the Society, the chairmen, and members of each of the standing committees have taken opportunity on every possible occasion to attend the meetings of the different branches of the State and County Societies and there present to them the activities of the Society thereby presenting an opportunity for discussion. We have earnestly tried to represent the Society in that matter.

In the attempt to improve the methods of the Executive Committee, we have attended the meetings and have met with the Board of Trustees and the chairmen of the standing committees. It has cost something to have

these men in, but we think it is economical because it has reduced the number of meetings of the committees.

A committee headed by Dr. Mitchell, has made very earnest effort in the last year to revise the constitution and by-laws of the Society. This revision will be presented for your consideration during this meeting, and whatever action you may take on it I wish you to thoroughly understand that this work represents the best thought of the leading members of our Society, and that these men have worked ardously and earnestly to do what they thought was best for the Society.

One of the gravest problems of the Society has been the relationship which the doctors maintain with the hospitals. This year, for the first time, we have had the opportunity of meeting representatives of the New York State Hospital Association so that the Committee from your Society could sit down with them at a table and present our problems and discuss them. As a result of those discussions we have settled nearly all of our problems. A few of these problems still remain because they will take a little more time. I recommend for your consideration that this committee should be maintained.

From the standpoint of legislation, the Society has enjoyed a peaceful year, thanks to the efforts of the chairman of the Legislative Committee and the members of his committee. Thirty-three pieces of legislation adverse to the Medical Society have been defeated and twelve constructive measures which we felt would promote the interest of the Society have been passed.

I am happy to tell you the most recent development in this field is the fact that the Governor has signed the Malpractice Act.

Your officers, chairmen and committeemen have earnestly endeavored to maintain, preserve, and advance a relationship which this Society maintains with the outside agencies throughout the year.

In closing, I again express to you the desire of the Medical Society of the County of Monroe, while acting as your host, to be of service to this House, and we hope you will have a successful meeting and that you will further advance the efforts of the Medical Society of the State of New York.

5 Address of the President-elect*Section 57*

DR. CHARLES H. GOODRICH, Kings Mr Speaker, Mr President, and members of the House of Delegates

These are crucial years for purveyors and consumers of modern medical service. Fate common to all is awaiting determination by public opinion. Public opinion awaits the adequate distribution of intelligence, truths wisely and clearly set forth by our profession. Moreover it awaits leadership which only physicians can give. Yet public opinion is often impatient—and the need is for prompt but unhasty

deliberation concerning vast matters far greater than any one revolutionary proposition such as Compulsory Health Insurance. Those laymen who for various selfish reasons would arrogate to themselves leadership in health and medical service repeat "when doctors disagree what can we conclude." Thus unity in thought and action are supremely desirable. Recommendations providing opportunity for such thought and action will shortly be offered by the Booth Committee, recently appointed by our President, Floyd Winslow.

The license to practice medicine implies greater obligation to the public than diagnosis of disease and treating patients for a consideration. What implications challenge our special interest during the coming year?

We often hear from members "What do I get from the County Society—or the State Society?" The answers are so many and obvious as to render repetition needless. The *spirit* prompting such remarks requires reformation. The questions of each and all members should be "how much can I *do* for my County Society or State Society, how much can I *put into* them?" Two to four per cent give generously of time and effort. Let us try to infuse this type of loyalty into the *entire membership* of our component county societies! Greater active constructive interest will produce enlarged influence.

In harmony with this let us ask, is our income adequate for our tasks? Are our dues in county societies and assessment in State Society for the realization and protection of our ideals commensurate with our income? The Union laborer pays from eight to fifteen times as much. The amount paid to New York State physicians as fees under the operation of the Compensation Law in 1936 was between eight and nine million dollars. Would two per cent of this be too much to expect?—\$160,000 to \$170,000? And how much per cent of the rest of our incomes? Altogether would ten, fifteen or even twenty cents a day be too much to dedicate to the maintenance of our position in the group relationships of the social structure? This is not only for our own sakes but for the public weal. This is something to think about and discuss. Limited funds in county or State may seriously limit accomplishment. We need more full time employees to be directed by our officers and committees and to place less dependence for detail work upon men whose careers are already overtaxing their hours and strength.

* * *

Four years is a brief time in which to provide a course in medicine. Graduating students have better technical education than ever before except in a department which includes *materia medica*, therapeutics, and pharmacology. It is often ridiculous and pathetic to watch a graduate of one to three years attempt to write a prescription. Sources of drugs, methods of preparation, physiological action, therapeutic application and dosages are all practically unknown to the otherwise up-to-the-minute rising

star. He is also unaware of incompatibles, symptoms and treatment of poisoning, Young's Rule, and like elementary information. Only the excessively detailed and abundantly sampled proprietaries and *insulin* are recognized. The principles of application of many forms of physiotherapy are unknown. We *recommend* that during the coming year considerable attention be given to *materia medica*, *therapeutics*, and *pharmacology* in scientific programs of our county and district meetings and county and state lecture courses. We further *recommend* that the Journal Management Committee be requested to establish in the NEW YORK STATE JOURNAL OF MEDICINE, a Department of *Materia Medica*, *Therapeutics* and *Pharmacology*, which may, in their wisdom, include articles by outstanding authorities in our profession, inquiries answered, therapeutic experiences, suggested methods of prescribing, and any other teaching by the written word which in its judgment will increase practical knowledge and skill in these subjects.

* * *

Although already initiated by your officers and committees, active *individual* cooperation with Health Departments and Health Officers seems indicated. In some large counties the Public Health Committees accomplish wonders. More wonders can be done by general membership insistence that all are live participants in the health projects of the community. The public expect this. Commissioners hope for it. Law implies our interest and cooperation. We are fit. There is much to be done. Behold what our Public Health Committee has accomplished under Dr Farmer. Every member can do his share in his own community. Every county society is urged to adequately enthuse its membership with the slogan "*Every Physician a Health Officer*"

* * *

Our profession is vocal concerning *Preventive Medicine*. Practically we have produced a certain few specific immunizing measures and have conducted campaigns to popularize them or to provide for required adoption by community or state. This is *specific* preventive medicine. Otherwise preventive medicine is a field so vast and so promising as to fascinate dreamer and worker. Ample reservoirs of information are reposing in our great libraries. What percentage of these are practically utilized? In what degree is the profession informed? How much have we taught our public?

When we say preventive medicine we mean all sorts of measures and provisions for preserving life and health. We include sanitation, hygiene, exercise, diet and drinkables, housing, ventilation, lighting, heating and, in general, the conduct of homes, schools, and institutions. We think of industrial diseases and injuries, street injuries, and accidents in sports. Also upper respiratory infections, epidemic and

endemic, precancerous irritations, focal infections of teeth and tonsils and their relations to arthritis and various infections of the respiratory and gastrointestinal tract. The degenerative diseases are increasing their toll of devoted tense workers especially among our own kind. Prevention of asphyxial deaths (including anesthesia) is an important item. Companion with this are the varying degrees of anoxemia suffered by many unconsciously and unnecessarily. We think of maternal welfare and the care of the healthy child. (In this we have made an appreciable start). Diseases of animals must be considered especially as transmissible to man. All of the infectious diseases can be reduced to a minimum, notably tuberculosis and syphilis. There is the physical welfare of the blind and deaf (ably studied by Dr. Hambrook's Committee). We think of the mentally deficient child and the too precocious child. Personal hygiene and mental hygiene are significant factors in complex living. Electricity including the x-ray menaces human safety. Also important is the hygiene of ports and ships that arrive and depart. Atmospheric pollution by smoke, dust, sand, carbon monoxide, and gases innumerable should be controlled. Moreover there are those numberless instances of acute infections and minor or major injuries in which prompt treatment in the hours of inception or reception may be *realistic* preventive medicine. Such treatment may prevent serious or critical illness, loss of time, earning power, and perhaps function, for the patient. As a corollary the physician would have many easy tasks instead of a few huge heartbreakers.

Preventive as well as curative medicine can be advanced by an increased percentage of recorded postmortem examinations. This may call for elaborate endeavor along special lines.

Thus is sketched all too incompletely the field of preventive medicine. Much of it can be cultivated for the *individual* by the masterly *complete* periodic health examination. This is an accepted procedure in theory but with low percentage in practice. If universally sought and practiced it would require the patient devotion of much time and great skill. In that day we must be ready with schedules, record blanks and equipment—material and mental—to do thorough work. When largely demanded by the people many specialists in this line will be needed. Therefore

We recommend that during the coming year in county and district branch meetings the subject of preventive medicine be actively presented, discussed, and that its practice by the profession be encouraged in every possible way, and

We recommend that contributions on preventive medicine to the STATE JOURNAL be offered by the membership and sought by the Journal Management Committee, and

We recommend that whenever and wherever possible lay audiences throughout the state be provided with addresses or lectures on preventive medicine, such provisions to be made by county societies, District Branch officers,

by the Public Relations Bureau of this Society, or by concerted action.

In connection with this last recommendation, may we remind you that preventive medicine can arrive at its goal only when an eager *enlightened public apply for it*. The enlightenment must come from us. We must convince them of the advantages obtainable.

I bespeak the valuable suggestions, sound advice, and cordial cooperation of the delegates and membership during the coming year.

THE SPEAKER This will be referred to the Reference Committee on the President's Report.

Since we last assembled this State has been honored in the National Organization by election to its highest office of one who has been very active among us, Dr. Chas. Gordon Heyd, president of the American Medical Association.

6 Address of the President of the American Medical Assn.

DR. HEYD Mr. Speaker, and members of the House of Delegates. I hope I am in no way changed from the time that you saw me at the last meeting of the House of Delegates except that I am possibly a year older, but still essentially unchanged.

It has been my good fortune to travel through many a state of this country and to see state societies working under the same conditions. I may say that the spirit that runs through organized medicine has never been so manifest as it is today, nor has there been a greater inspiration to preserve the best features of medical service in the practice of medicine. Therefore I feel that medicine is marching forward triumphantly and courageously.

It gives me very deep pleasure, Mr. Speaker, to bring to you personally and to the House of Delegates this very small implement of social organization. (*Presenting an inscribed gavel to Dr. Kopetzky*) Two thousand years of law and order are represented in this gavel.

On behalf of the American Medical Association we wish you a most successful session.

THE SPEAKER Thank you, Dr. Heyd. Since we last met there are two men who have been honored by the American Medical Association. One is the speaker of the American Medical Association, Dr. Van Ethen, and the other is Dr. Cunniffe of the Bronx who has joined an important committee on Judiciary in the American Medical Association.

7 Introduction of Guest

THE SPEAKER I want to welcome as our guest a distinguished medical man, Dr. William P. Waring, of Omaha, Nebraska.

DR. WARING Mr. Speaker and members of the House of Delegates. I am deeply appreciative of this honor. I know that you are going to have a busy session and I hope to gain a lot by watching this house in action.

8 Supplementary report of the Treasurer

Section 33

DR. GEORGE W. KOSMAK, *Treasurer* The audit of the Society's treasury is dated December 31, 1936, as this marks the conclusion of its fiscal year. As noted in my published report this indicates an excess of income over expenditures of \$17,646 55, which was transferred to the surplus account. This sum includes an item of approximately \$8,700 from interest on invested funds and of about \$2,400 of gain from the sale or calling in of securities. The actual margin between dues collected from the membership and expenditures during the fiscal year is only about \$6,300. Appropriations authorized during the current year since January first for additional committee expenditures and other purposes total a sum of \$4,000 and over.

Your treasurer desires to repeat a warning conveyed in his original report and which is now strengthened by the events of recent months, that your Society must assure itself of a larger margin between income and expenditure. Invested funds cannot be relied upon in the near or even distant future to yield an adequate return to meet whatever extraordinary demands may be made upon your treasury by a financial or other catastrophe. An organization of the size and importance of the Medical Society of the State of New York must assure itself of a larger cash surplus in particular, to meet such contingencies. It cannot be operated successfully or with dignity on such a narrow margin of safety. One of the ways to solve the situation is to scale down on expenditures by whatever laudable efforts your officers and delegates may find it possible to employ. Another is to increase the Society's membership and the final and least desirable is to levy an additional assessment. The latter should only be regarded in the light of a final resort.

This supplementary report is submitted for your respectful consideration and action.

THE SPEAKER Referred to the Committee on Report of the Treasurer

9 Supplementary report of Executive Committee

DR. PETER IRVING, *Secretary* To the House of Delegates, Gentlemen

The Executive Committee submits a supplementary report on certain matters brought to conclusion following its report of April 1, 1937

MEDICAL EXPENSE INDEMNITY INSURANCE

Study of this matter throughout the year led to the formulation, as indicated in the previous report, of the following resolutions passed on February 11, 1937

1 We define Medical Expense Indemnity Insurance as a form of insurance whereby an individual, by making payments of stated premiums, purchases a definite sum of money in cash, which is thus made available to him

for the payment of the individual's physician's charges for professional services. We recommend endorsement of such a form of insurance

2 We would add that in our opinion the physician's claims for his professional services should be a first lien on the cash indemnity

3 That the Medical Expense Indemnity Insurance Plan must be carried out on an actuarial basis

4 That philanthropy has no place in a Medical Expense Indemnity Insurance scheme or plan to deliver cash benefits to those who pay its premium requirements, so as to have funds to meet physicians' charges for services

At this time the Executive Committee instructed the Committee on Economics to formulate a model bill in detail complete on a non-profit Medical Expense Indemnity Insurance Plan and submit it to the Executive Committee for consideration. The Committee on Economics then drew up and submitted a proposed amendment to the Insurance Law for the purpose of legalizing Medical Expense Indemnity Insurance as follows

An Act

To amend the Insurance Law and the Membership Corporation Law, in relation to Non-Profit Medical Expense Indemnity Corporations

The people of the State of New York, represented in Senate and Assembly, do enact as follows

Section 1 Chapter thirty-three of the Laws of nineteen hundred nine, entitled "An Act in Relation to Insurance Corporations, Constituting Chapter twenty-eight of the Consolidated Laws" is hereby amended by adding thereto a new Article, to be Article Fifteen, to read as follows

ARTICLE 15

NON-PROFIT MEDICAL EXPENSE INDEMNITY CORPORATION

§ 470 *Definition and Scope of Article* Any corporation heretofore or hereafter organized under the Membership Corporation Law of the State of New York to be known as a Non-Profit Medical Expense Indemnity Corporation for the purpose of establishing, maintaining and operating a Non-Profit Medical Expense Indemnity Plan whereby members shall be indemnified to an amount not exceeding three hundred dollars in any one policy year, for amounts paid out or agreed to be paid out by them for medical and/or surgical care and treatment and nursing care, under the terms, limitations and conditions of membership certificates issued to them after the conditions, limitations and terms and premium rates of such membership certificates have been approved by the Superintendent of Insurance, shall be governed by this Article and shall be exempt from

all other provisions of the Insurance Law of this State, unless specifically designated herein, not only in governmental relations with the State but for every other purpose and no additions or amendments hereto, hereafter enacted, shall apply to them unless so expressly designated therein. The Superintendent of Insurance may require any such Non-Profit Medical Expense Indemnity Corporation to establish and maintain the same reserves for the protection of members as are required to be maintained by stock insurance corporations in relation to insurance of a similar class, except that the Superintendent may be governed by the provisions of subdivision one of subdivision B of section three hundred forty-four of this Chapter in setting up the reserves of any such corporation. The Superintendent of Insurance may require reinsurance in such form and amount in a stock insurance corporation as the circumstances of risk may require to assure solvency of a Non-Profit Medical Expense Indemnity Corporation confronted by unusual or catastrophic losses

§ 471 *Incorporation.* 1 Persons desiring to form a Non-Profit Medical Expense Indemnity Corporation shall incorporate under the provision of Article two of the Membership Corporation Law of the State of New York.

2 At least two-thirds of the directors of such corporation chosen at the first annual and each subsequent meeting at which directors are chosen, shall be selected from a list of persons nominated by a Committee designated for such duty by the local County Medical Society in which such Medical Expense Indemnity Corporation maintains its principal office, except when there is no local County Medical Society and/or when a local County Medical Society shall fail or refuse to designate such nominating committee, the governing body of the Medical Society of the State of New York shall designate such nominating committee, and/or when more than twenty-five percent of the membership of such Non-Profit Medical Expense Indemnity Corporation is resident in two or more Counties then the nominating committee shall be designated by the Medical Society of the State of New York.

3 Every certificate of incorporation of a Non-Profit Medical Expense Indemnity Corporation filed pursuant to the provisions of the Membership Corporations Law of the State of New York shall have endorsed thereon or annexed thereto the consent of the Superintendent of Insurance of the State of New York and the State Department of Social Welfare as provided in the Membership Corporations Law

§ 472 *Annual Reports of Corporations* Every such corporation shall annually on or before the first day of March file in the office of the Superintendent of Insurance a statement verified by at least two of the principal officers of said corporation showing its condition on the thirty-first day of December, then next preceding, which shall be in such form and

shall contain such matters as the Superintendent shall prescribe.

§ 473 *Examinations* The Superintendent of Insurance, or any deputy or examiner or any other persons whom he shall appoint, shall have the power of visitation and examination into the affairs of any such corporation and free access to all the books, papers and documents that relate to the business of the corporation, and may summon and qualify witnesses under oath to examine its officers, agents or employees or other persons in relation to the affairs, transactions and condition of the corporation

§ 474 *Acquisition Costs* All acquisition costs in connection with the solicitation of subscribers to Medical Expense Indemnity Plans shall at all times be subject to the approval of the Superintendent of Insurance

§ 475 *Funds* The funds of any corporation subject to the provisions of this Article shall be invested only in securities permitted by the Law of this State for the investment of assets of Life Insurance Companies

§ 476 *Dissolution and Liquidation* Any dissolution or liquidation of a corporation subject to the provisions of this Article shall be under the supervision of the Superintendent of Insurance who shall have all power with respect thereto granted to him under the provisions of Article eleven of this Chapter

§ 477 *Taxation* Every corporation subject to the provisions of this Article is hereby declared to be a charitable and benevolent institution, and all of its funds shall be exempt from every state, county, district, municipal and school tax other than taxes on real estate and office equipment.

§ IV Subdivision One-B of Section eleven of Chapter forty of the Laws of nineteen hundred nine, entitled "An Act in Relation to Membership Corporations, Constituting Chapter thirty-five of the Consolidated Laws" as added by Chapter three hundred twenty of the Laws of nineteen hundred thirty-five, is hereby amended to read as follows

1-B If Certificate of Incorporation specifies among its purposes the establishment, maintenance and operation of a Hospital Service Plan or a Medical Expense Indemnity Plan as permitted under Article fourteen of the Insurance Law, the consent of the Superintendent of Insurance and the State Department of Social Welfare shall be endorsed thereon or annexed thereto

§ 4 This Act shall take effect immediately

* * *

With the above draft the Committee on Economics submitted the following explanatory comments as a guide to discussion on Medical Expense Indemnity Insurance and its supervision and regulation

1 Medical care is a service and not a commodity. In the nature of its creation and maintenance it is unlike and apart from all other human relations in which materials and ser-

vices are exchanged It is a *necessity of life* which does not admit of variation of quality without serious prejudice to the interest of the receiver

Quality of Medical Care rests upon the physician's individual aptitude and intelligence, preparatory education and training, individual integrity, and environmental economic conditions The variable expressions of each disease disorder, and the variable reactions of each individual to injury and other conditions which influence the state of health, preclude inflexible standardization of procedure Medical care must always remain the practice of the art of adaptation of methods and principles to the personal problems as presented in an individual

Therefore, regulation and supervision of Medical Care must take into account inevitable humanistic vagrancies of personal conduct on the part of both the one who receives and the one who renders medical care.

In undertaking to establish ways and means of meeting the costs of good medical care, especially for the lower income levels of a community, thru some plan of collective action or organization of interests, such as by medical expense indemnity insurance, some provision for the general maintenance of the highest quality of service must be made

WHO SHOULD BE INVESTED WITH SUCH RESPONSIBILITY AND AUTHORITY? Can any layman or board of laymen successfully undertake such function? Without complete understanding of the sciences and technics of medical practice, and without the knowledge that arises from practical experience of intimate contact with the responsibilities and problems of medical practice, such authority must fail to serve the true interests of the injured and sick.

The question arises, therefore, by what practical program or plan can the conduct of medical care be safeguarded by the medical profession? Since the public, collectively and individually, trust their lives and health in the confidence of medical men, may they not well trust the general control of medical conduct in the collective action of the medical profession as represented in the organized medical societies?

CONCLUSIONS The first step in the establishment of a non-profit mutual association of laymen for the application of Medical Expense Indemnity Insurance should be the establishment of contractual relation between the insurance group of the local County Medical Society for the founding of cooperation of such local County Medical Society in the operation of the plan or, with the State Medical Society when the operations of the association extend into two or more counties

2 THE CONTRACT should include Articles on the following items

(a) Provision of a panel of physicians who agree to abide by rules of conduct prescribed by the Medical Society, who agree to abide by rules of conduct, and abide by arbitration

settlement of any disputes or differences which may arise out of the care of insured patients

(b) Acceptance by the Insurance association of the arbitration settlement of any differences arising out of the contractual relationships

(c) Definition or specification of health and medical care problems which are to be included under the insurance coverage.

(d) A schedule, or schedules, of fees for services which may be rendered under the terms of the insurance coverage, and provision for the revision of such schedules from time to time, that they may be adjusted to any change in general economic conditions

(e) Provision by the Medical Society of a list of nominees for the directorate of the insurance association

(f) The insured shall exercise free choice in the selection of attending physician, within range of the panel established by the Medical Society

(g) Exemptions for emergent care, for domiciliary care and needs of insured while temporarily resident outside the home community shall be defined.

(h) The association shall make no contract with the physician or group of physicians for medical care of insured members other than as herein specified

3 ORGANIZATION OF ASSOCIATIONS Each association should be required to file with the State Insurance Department a Constitution and By-laws which shall conform to the following standards

(a) *Size* The number of insured in any one association should be limited to 5,000 persons, and/or to the residents of one community (rural), to the employees of one industrial organization

(b) *The Officers* of the association should be limited to persons who by residence, occupation or otherwise are closely related or associated with the members of insured, and who by reason of which are personally familiar with the daily life and habits and general conditions under which the insured live. Officers shall be elected by vote of the insured

(c) The association shall be incorporated as a non-profit mutual association, and shall be self-reliant as to financial resource

(d) The association shall not contract to provide any form of medical treatment and/or diagnosis service

(e) The association shall contract with its members only to provide certain sums of money to satisfy the obligations of the insured for medical diagnostic or surgical care

(f) The association shall impose no obligation or regulations upon medical attendants of the insured except thru the agency of the local County Medical Society

(g) Two-thirds of the governing board of the association shall be chosen from the list of candidates nominated by the local County or State Medical Society

(h) The association shall require from the applicant for membership a certificate from any and all physicians who have attended or ex-

anned such applicant within the twelve months next preceding, attesting that there is no known pending need for medical or surgical care, and/or the applicant shall sign a waiver against such specific need, if there be a known need. A fraudulent or deliberate mis-statement by the applicant or a medical attendant shall void the obligations of the association.

(i) Extension or retrenchment of coverage shall be made only upon agreement with the local County or State Medical Society, and upon sound actuarial appraisal, and not without sanction of the Superintendent of Insurance.

(j) The association shall not contract to indemnify the expense of minor or trivial ills, nor for the initial expense of major ills. The exact limits of initial expense to be borne by the insured to be determined according to the premium benefit schedules agreed upon between the association and the Medical Society, and approved by the Superintendent of Insurance.

(k) Such association shall not agree to provide other benefits particularly it shall not provide any benefit in cash or otherwise for the loss of income incident to unemployment arising out of illness.

(l) The association shall not provide indemnity benefits for care of any insured in an institution not approved by the Medical Society.

(m) The association shall limit its membership and the participation in its benefits to persons of prescribed limits of personal or family income according to agreement with the Medical Society, and as approved by the Superintendent of Insurance.

(n) The association shall contract with the State Medical Society as a party of interest when twenty-five per cent or more of its members reside in another County than that in which the association has its principal office.

(o) The association shall protect its financial stability against unusual or catastrophic losses by "re-insurance" in a stock insurance company, in such form and amounts as may be required by the Superintendent of Insurance, according to the circumstances of each association.

4 AUTHORITY AND RESPONSIBILITY OF MEDICAL SOCIETIES (a) Panel Each County Medical Society shall designate a committee whose duty it shall be to list any duly registered physician who desires to participate in the professional care of insured members of the association, according to his qualifications and experience, and who agrees to abide by such rules and regulations as the Society may from time to time establish for the supervision and regulation of the conduct of physicians. The Society shall have authority to collect such reasonable annual fee for such listing as may be necessary for the costs of administration.

(b) The Society thru a designated committee shall have the right to investigate the conduct of any panel physician upon complaint of the association of an insured member, or by its own initiative.

(c) A physician shall be removed from the panel of participating physicians by the designated committee of the Medical Society when it shall find, after reasonable investigation, that said physician

(1) has been guilty of professional or other misconduct or incompetence in connection with medical care rendered an association insured patient, or

(2) has rendered medical or surgical service to a member of the association under the terms of this insurance for a fee less than the prescribed minimum standard of the schedule of fees, or

(3) has participated in the division, transference, assignment, rebating, splitting or refunding of a fee for medical service under the terms of the Medical Society—Association contract, or

(4) has solicited, or has employed another to solicit for him or for another the professional treatment, examination or care of an insured member of the association, or

(5) has been removed from the panel of physicians authorized by the *Local County Medical Society* to render medical care to injured workmen under the provisions of Chapter 258 of the Laws of New York State.

(6) a physician under disciplinary sentence may appeal for re-hearing by the committee or governing body of the Medical Society, and the decision of that body shall be final.

(d) The designated committee shall have power to negotiate and from time to time revise the schedule or schedules of fees for medical service.

(e) The governing body of the local County or State Medical Society shall establish rules of procedure for arbitration of issues of difference or conflict arising out of this contractual relationship between insured members of the association and members of the panel participating physicians.

(f) Issues of dispute or conflict between the association and the Medical Society shall be settled by arbitration under rules prescribed by the Superintendent of Insurance.

5 MEDICAL EXPENSE INDEMNITY INSURANCE COUNCIL. Under the Superintendent of Insurance, there shall be established an advisory body for the consideration of problems developing out of experience of organization or administration of Medical Expense Indemnity Insurance. The Council shall be composed of nine members, one representing the Superintendent of Insurance who shall be the Chairman, one representing the Department of Social Welfare two other than Society officers representing the association membership three representing local County Medical Societies and two representing the Medical Society of the State of New York.

The duty of this Council shall be to study the application of this principle of insurance to the social problems of medical care for the people of low income, and to make recommenda-

tion to the Superintendent of Insurance for the proper supervision and regulation under authority of the State Insurance Commission

The Executive Committee then gave permission to the Committee on Economics "to carry on negotiations in this connection with the State Department of Insurance with the provision that the Committee on Economics not commit the State Society to anything based on the negotiations until the Executive Committee has acted thereon" Pending the report of such negotiations the Executive Committee postponed action on the entire matter of Medical Expense Indemnity Insurance and legislation pertinent thereto

On April 8, 1937, the Chairman of the Committee on Economics reported in detail on the conference with Mr Taylor of the State Insurance Commission concerning the Enabling Bill previously submitted to the Executive Committee. It was clear from this report that the attitude of the Insurance Commission was apparently cordial to the idea of Medical Expense Indemnity Insurance as detailed above. It is known that in the administration of Insurance Companies the State Commission is primarily interested in their efficient operation at low expense and their continued solvency and ability to pay claims as well as their fair treatment of the Public

CONFERENCE WITH THE STATE HOSPITAL ASSOCIATION

Subsequent to the previous report a further conference of sub-committees was held and the following report is submitted which embraces certain definite Articles of Agreement. These Articles are to be presented to the State Hospital Association for its action on May 20, 1937

Article I

The Hospital as such should not provide Medical Care a Hospitals should not themselves hereafter enter into agreements to provide medical care for any groups, persons or associations

That the question of the definition of "Medical Care" be tabled until the members have an opportunity to consult a copy of the "Medical Practice Act"

b Before entering into any contract or agreement where medical care is provided, the medical staff of the hospital and the organized medical group of the community should agree as to the ethical and economic wisdom of the proposal.

c. Where agreements are reached as in (b) the fee schedule should be used as a standard and guide for persons of a like standard of living

Article II

Hospitals should, in agreement with representatives of the local County Medical Societies, set up financial eligibility standards for ward and dispensary care

a Indigent patients should be treated professionally without charge as at present. This rule will be altered at any time when provisions are made for remuneration of physicians

b All patients within the range of the financial eligibility standards agreed upon should be treated in the wards of the hospital. The hospital may charge a maximum *per diem* fee agreed upon for ward care

c All patients above the agreed eligibility standards set for ward care should be the private patients of the members of the staff of the hospital. In such cases the physician should render his own bill after making his own arrangements as to a fee.

Article III

Pay clinics should be abolished by all hospitals and clinics

(Left Open for Final Phrasing)

a The financial eligibility standards for outpatient departments should be rigidly enforced

b The outpatient department should not be operated in such a manner as to compete with private practitioners of medicine.

c. The fees for admission to outpatient departments and other fees charged for diagnostic and other service in the clinic should be minimal fees not designed to provide a profit to the institution and not competitive with the private practitioner of medicine

d For equal services these fees should be uniform for the community and set after conference with the local County Medical Society

Article IV

Hospitals should abide by the spirit and the letter of the Workmen's Compensation Law and cooperate with representatives of the local County Medical Society in all matters pertaining thereto

Article V

The scope of full time physicians in hospitals should be carefully defined

a Such physicians should not compete with private practitioners of medicine in the treatment of private patients in the hospital

b The relation of full time physicians to the volunteer staff should be defined.

Article VI

Hospitals should not for the purpose of creating hospital income provide diagnostic or therapeutic services, in the auxiliary branches, to the general public.

Such services, however, may be made available where necessary upon the request of local practicing physician.

Nothing herein contained should be regarded as forbidding or discouraging the rendering by the hospital, without profit, of needed technical services which private practitioners themselves are unable to supply

Article VII

Hospital groups in each community should set up a conference or coordinating council with representatives of the County Medical Society and local hospitals to discuss matters of mutual interest and to carry out the recommendations mutually agreed upon.

Article VIII

A code of ethics for hospitals should be developed. Hospitals should not advertise or utilize the work of their professional staffs to advertise the institution.

Article IX

Hospitals should adopt a uniform cost accounting and bookkeeping system for the determination of the cost of hospital service.

a. This is imperative in developing good cost accounting throughout the hospital system and in clarifying departmental costs and establishing their bearing on the costs of medical care, and such costs should be made available to any member of the staff

Article X

Agreements with organized medicine in relation to the Associated Hospital Service, or similar services, should be faithfully carried out in letter and in spirit.

a. What constitutes "ordinary" x-ray and laboratory service should be defined and made uniform for the entire region or state.

Article XI

In all matters of legislation and proposed legislation uniting the interests of the hospital or the medical profession, the hospitals and the organized medical profession should confer in advance and both parties should act in conformity with such agreement and within the range and scope of the principles agreed upon.

Article XII

Hospitals should urge membership in the organized medical group for all members of the hospital and dispensary staffs who are eligible for such membership and who are in the private practice of medicine, and should take into consideration any action by a County Society against a member for unprofessional conduct.

The above Articles indicate the studied and final conclusions of the conferees. There are other matters that have been considered but which have not as yet been decided. Among these are questions of definition of "ordinary x-ray and laboratory service" as described in the Associated Hospital Service Certificate. A sub-committee of three from each group will begin discussion of this problem on May 17, 1937.

Problems that have arisen in relationship of radiologists and hospitals await future solution in the light of opinions now under consideration by the Council of the American Medical Association and the Trustees of the American Hospital Association.

APPOINTMENT OF REPRESENTATIVES TO THE ANNUAL MEETING OF THE CONNECTICUT STATE MEDICAL SOCIETY

The Connecticut State Medical Society formally requested the Medical Society of the State of New York to appoint two representatives to attend its Annual Meeting on May 19 and 20, 1937.

The Executive Committee looked favorably upon this request and authorized the President to appoint two representatives.

SPECIAL COMMITTEE TO CONSIDER PROVISION OF MEDICAL CARE

On May 13, 1937, the Executive Committee authorized the President to appoint a Special Committee for the purpose of considering principles which should in the light of present knowledge govern provision of medical care. On notification by the President the following Committee was selected:

Arthur W. Booth, <i>Chairman</i>	Elmira
Andrew Sloan	Utica
Edward E. Haley	Buffalo
Edward T. Wentworth	Rochester
Thomas A. McGoldrick	Brooklyn
Samuel J. Kopetzky	New York
Floyd S. Winslow, (ex-officio)	Rochester
Peter Irving, (ex-officio)	New York

THE SPEAKER Referred to Reference Committee on Reports of Secretary, Council, Censors and Councillors

10 Definition of the Term "Ordinary X-ray"

THE SECRETARY I A sub-committee of the conferees of the New York Medical Society and the New York Hospital Association, appointed to define the term "ordinary x-ray" used in group hospital insurance contracts, are agreed that it would be better to exclude such service from future agreements as early as possible, or to provide in such contracts for

tion to the Superintendent of Insurance for the proper supervision and regulation under authority of the State Insurance Commission

The Executive Committee then gave permission to the Committee on Economics "to carry on negotiations in this connection with the State Department of Insurance with the provision that the Committee on Economics not commit the State Society to anything based on the negotiations until the Executive Committee has acted thereon." Pending the report of such negotiations the Executive Committee postponed action on the entire matter of Medical Expense Indemnity Insurance and legislation pertinent thereto

On April 8, 1937, the Chairman of the Committee on Economics reported in detail on the conference with Mr Taylor of the State Insurance Commission concerning the Enabling Bill previously submitted to the Executive Committee. It was clear from this report that the attitude of the Insurance Commission was apparently cordial to the idea of Medical Expense Indemnity Insurance as detailed above. It is known that in the administration of Insurance Companies the State Commission is primarily interested in their efficient operation at low expense and their continued solvency and ability to pay claims as well as their fair treatment of the Public

CONFERENCE WITH THE STATE HOSPITAL ASSOCIATION

Subsequent to the previous report a further conference of sub-committees was held and the following report is submitted which embraces certain definite Articles of Agreement. These Articles are to be presented to the State Hospital Association for its action on May 20, 1937

Article I

The Hospital as such should not provide Medical Care a Hospitals should not themselves hereafter enter into agreements to provide medical care for any groups, persons or associations

That the question of the definition of "Medical Care" be tabled until the members have an opportunity to consult a copy of the "Medical Practice Act"

b Before entering into any contract or agreement where medical care is provided, the medical staff of the hospital and the organized medical group of the community should agree as to the ethical and economic wisdom of the proposal

c Where agreements are reached as in (b) the fee schedule should be used as a standard and guide for persons of a like standard of living

Article II

Hospitals should, in agreement with representatives of the local County Medical Societies, set up *financial eligibility standards for ward and dispensary care*

a Indigent patients should be treated professionally without charge as at present This rule will be altered at any time when provisions are made for remuneration of physicians

b All patients within the range of the financial eligibility standards agreed upon should be treated in the wards of the hospital The hospital may charge a maximum *per diem* fee agreed upon for ward care

c All patients above the agreed eligibility standards set for ward care should be the private patients of the members of the staff of the hospital In such cases the physician should render his own bill after making his own arrangements as to a fee.

Article III

Pay clinics should be abolished by all hospitals and clinics

(Left Open for Final Phrasing)

a The financial eligibility standards for outpatient departments should be rigidly enforced

b The outpatient department should not be operated in such a manner as to compete with private practitioners of medicine

c The fees for admission to outpatient departments and other fees charged for diagnostic and other service in the clinic should be minimal fees not designed to provide a profit to the institution and not competitive with the private practitioner of medicine

d For equal services these fees should be uniform for the community and set after conference with the local County Medical Society

Article IV

Hospitals should abide by the spirit and the letter of the Workmen's Compensation Law and cooperate with representatives of the local County Medical Society in all matters pertaining thereto

Article V

The scope of full time physicians in hospitals should be carefully defined

a Such physicians should not compete with private practitioners of medicine in the treatment of private patients in the hospital

b The relation of full time physicians to the volunteer staff should be defined

Article VI

Hospitals should not for the purpose of creating hospital income provide diagnostic or therapeutic services, in the auxiliary branches, to the general public.

pliable for all portions of the state, owing to the many varying conditions. The need for further regional conferences in other portions of the State is evident.

Maternal Welfare Postgraduate courses on Obstetrics have been sponsored by the Society in five counties and one course was arranged by a county medical society, aided by our Committee. The State Department of Health is appropriating funds for the payment of expenses for the courses in four counties. As a result of a lecture sponsored in St. Lawrence County, and of attendance of representatives of this county at a regional conference on Child Hygiene in Watertown, a maternal mortality study has been started in that county. In connection with all of the courses on Obstetrics, plans for an active maternal welfare campaign are being formulated in these counties. Undoubtedly, regional conferences in various portions of the state is the ideal way to further this work.

Miscellaneous The Committee has made available to the administration in one county, advice regarding physical examination of N. Y. A. youths. As a result of the aid of the Committee on Public Health and Medical Education in supervising the physical examinations of 4-H Club boys and girls at the New York State Fair in September 1936, the Committee has been requested to advise in the formulation of a plan for the physical examination of the members of the county organizations of this club.

The Committee on Public Health and Medical Education met in Auburn on March 31, 1937, at the request of the officers of the Cayuga County Medical Society to advise that Society regarding a program setting up a division of maternal and child welfare in the Auburn City Department of Health. Subsequent to this meeting, the Cayuga County Medical Society approved such a plan.

At this meeting it was moved that the following resolution be submitted to the House of Delegates

"WHEREAS, motion picture films are being offered both free of charge and on a rental basis, by organizations, commercial and non-commercial, for programs of county medical societies, and in some instances with speakers, and

"WHEREAS, some of these motion picture films carry advertising matter or propaganda to which objection might be raised,

"Be It Resolved that the House of Delegates of the Medical Society of the State of New York, in annual session convened at Rochester, New York, this 24th day of May, 1937, request the House of Delegates of the American Medical Association to make provision for the review and classification of films and other similar material offered for programs of county medical societies so that information regarding them may be available to county medical societies,

"Be It Further Resolved, that the delegates from New York State to the annual meeting of the American Medical Association at Atlantic City on June 7, 1937, be instructed to pre-

sent and to further the passage of the foregoing resolution"

THE SPEAKER Referred to the Reference Committee on Public Health and Medical Education.

12 Supplementary report of Committee on Medical Trends

Section 49

DR. TERRY M. TOWNSEND, *New York* To the House of Delegates, Gentlemen Since April 1, the date of preparing the formal report to you of the work of this committee, additional progress has been made which is deemed worthy to be called to your attention.

The committee has prepared and mailed two issues of the "Speaker's Service Bulletin" and three issues of its "Spot Speaker's Service Bulletin" as follows No 1, "Tuberculosis Is Still a Serious Problem" No 2 April 3, "Anything Can Happen!" No 3, April 24, "Mother's Day" No 4, May 1, "The Doctor and the Public", No 5, May 12, "The Battle is Not Yet Won."

Numbers 1 and 3 were regular Bulletins, numbers 2, 4, and 5, "Spot" Bulletins, the distinction being that the latter have a timely and immediate usefulness in a higher degree than the usual bulletins

It is planned by the use of this method of presentation to emphasize one subject at a time, taking advantage of current popular thinking to present our ideas at the time they will receive the most widespread acceptance. Thus is avoided the academic attitude of indifference to timely current events while at the same time nothing in educational value is lost.

The function of these bulletins may be indicated by quoting from the explanatory description printed on the cover of each issue

"Physicians as a class are more influential in their communities than any other group. They have little time to address themselves to the technique of utilizing their influence. This service will aim to offer concrete specific suggestions to make it more easily possible for the doctor to exert the power of moulding public opinion which he already possesses

"The service will provide

"1 Subjects for talks before groups or over radio, with outline of speeches, and sample completed talks

"2 Ideas and suggestions for developing local speaker's bureaus in county medical societies, practical hints on speaking in public, timely topics which will interest certain groups on special occasions

"3 Suggestions for assisting the doctor in appropriately commenting on quasi-medical matters of timely public interest in the course of his usual day to day contacts at club, church or elsewhere."

Reprints were obtained of the article in the May issue of *Nation's Business* entitled "Uncle

the payment of hospital, of roentgenologist, of pathologist and of anesthetist for their services

II In the meantime, the conferees believe that the term "ordinary" now in current contracts should be understood to cover only that minimum of diagnostic x-rays and laboratory examinations required for institution of therapy for the ailment for which the patient was admitted to hospital

THE SPEAKER Referred to Reference Committee on Report of Committee on Public Health and Medical Education

11 Supplementary report of the Committee on Public Health and Medical Education

Section 77

DR. FARMER The Committee on Public Health and Medical Education begs leave to submit the following supplementary report for the year 1936-1937

Graduate Education

The following is the corrected list of county societies in which graduate courses have been sponsored by the Committee during the current year

Cattaraugus	Obstetrics
Cayuga	General Medicine
Chemung	Syphilis
Clinton	Gastroenterology
Franklin	Gastroenterology
Herkimer	Obstetrics
Jefferson	Obstetrics
Madison	Internal Medicine
Monroe	General Medicine
Montgomery	Obstetrics
Rockland	Obstetrics
St Lawrence	Miscellaneous
Steuben	Syphilis
Sullivan	Orthopedic Surgery
Tioga	General Medicine
Wayne	General Medicine

The courses now being given in Clinton, Franklin, Herkimer, Madison, and Montgomery Counties will not be completed until some time after the annual meeting of the State Society. Columbia, Greene, Otsego, and Schoharie County Societies requested courses. Information was furnished these Societies regarding available courses, but no selection of a course was made.

Public Health

Pneumonia Control As mentioned in the regular report, the program on pneumonia control was sent to county medical societies with a letter on this subject. Replies were received from several county societies indicating an active interest.

The Chairman appeared at a hearing before the Senate Finance Committee in Albany, in support of a bill to further appropriations for pneumonia control work, and on the same day

attended a conference called by the Governor to consider the same purpose. As a result of this hearing and conference, a bill was passed by the Legislature and signed by the Governor, appropriating \$400,000.00 for the purpose of providing to physicians all types of pneumonia serum and making further studies in pneumonia control.

Syphilis Control The Committee has sponsored graduate courses on syphilis which were given to the members of the Chemung and Steuben County Medical Societies. As a result of this activity the Committee has been advised by the State Department of Health that it will make an appropriation to cover graduate education in syphilis to be sponsored jointly by that Department and this Committee of the State Medical Society.

Cancer Control A bill has been passed by the Legislature, providing for a commission to study cancer. This commission is to be composed of three members of the Senate, three members of the Assembly, and three members to be appointed by the Governor, one of whom is to be the State Commissioner of Health. At a meeting of the Committee on Public Health and Medical Education at the time this bill was introduced, the following motion was made, seconded and carried.

"It is our opinion that, since cancer is primarily a medical problem, a Commission to study this problem should be composed predominantly of medical men, similarly to the methods used in the study of the problems of syphilis and pneumonia, which have been well handled by joint advisory commissions composed of members of the medical profession and health groups."

It was further moved, seconded, and carried in the event of the passage of a bill providing for a Commission to study cancer, the Chairman of this Committee is authorized to advise the House of Delegates of the desirability of designating the Committee on Public Health and Medical Education to represent the State Medical Society at hearings to be held under the provisions of the bill, also as to the desirability of providing funds which will be needed by this Committee to obtain the information necessary and which will be expected of the medical group.

The Committee in conjunction with the Executive Officer is already acquiring information which it will be in a position to present to this commission when and if appointed.

Child Hygiene The sub-committee on Child Hygiene has held regional meetings in Buffalo and Watertown, which have provided the Committee with much information and have undoubtedly promoted interest in this matter among the representatives of the various county medical societies. Consideration has been given at these conferences to prematurity, nutrition, preventive inoculations, tuberculosis, examinations of pre-school and school children, the need of nursing service and problems connected with Child health clinics. Apparently a standard program on Child health would not be ap-

pliable for all portions of the state, owing to the many varying conditions. The need for further regional conferences in other portions of the State is evident.

Maternal Welfare Postgraduate courses on Obstetrics have been sponsored by the Society in five counties and one course was arranged by a county medical society, aided by our Committee. The State Department of Health is appropriating funds for the payment of expenses for the courses in four counties. As a result of a lecture sponsored in St. Lawrence County, and of attendance of representatives of this county at a regional conference on Child Hygiene in Watertown, a maternal mortality study has been started in that county. In connection with all of the courses on Obstetrics, plans for an active maternal welfare campaign are being formulated in these counties. Undoubtedly, regional conferences in various portions of the state is the ideal way to further this work.

Miscellaneous The Committee has made available to the administration in one county, advice regarding physical examination of youths. As a result of the aid of the Committee on Public Health and Medical Education in supervising the physical examinations of 4-H Club boys and girls at the New York State Fair in September 1936, the Committee has been requested to advise in the formulation of a plan for the physical examination of the members of the county organizations of this club. The Committee on Public Health and Medical Education met in Auburn on March 31, 1937, at the request of the officers of the Cayuga County Medical Society to advise that Society regarding a program setting up a division of maternal and child welfare in the Auburn City Department of Health. Subsequent to this meeting, the Cayuga County Medical Society approved such a plan.

At this meeting, it was moved that the following resolution be submitted to the House of Delegates

"WHEREAS, motion picture films are being offered both free of charge and on a rental basis, by organizations, commercial and non-commercial, for programs of county medical societies, and in some instances with speakers,

"WHEREAS, some of these motion picture films carry advertising matter or propaganda to which objection might be raised,

"Be It Resolved that the House of Delegates of the Medical Society of the State of New York, in annual session convened at Rochester, New York, this 24th day of May, 1937, request the House of Delegates of the American Medical Association to make provision for the review and classification of films and other similar material offered for programs of county medical societies, so that information regarding them may be available to county medical societies,

"Be It Further Resolved, that the delegates from New York State to the annual meeting of the American Medical Association at Atlantic City on June 7, 1937, be instructed to pre-

sent and to further the passage of the foregoing resolution"

THE SPEAKER Referred to the Reference Committee on Public Health and Medical Education.

12 Supplementary report of Committee on Medical Trends

Section 49

DR. TERRY M. TOWNSEND *New York* To the House of Delegates, Gentlemen Since April 1, the date of preparing the formal report to you of the work of this committee, additional progress has been made which is deemed worthy to be called to your attention

The committee has prepared and mailed two issues of the "Speaker's Service Bulletin" and three issues of its "Spot Speaker's Service Bulletin" as follows No 1, "Tuberculosis Is Still a Serious Problem", No 2 April 3 "Anything Can Happen!" No 3 April 24, "Mother's Day", No 4, May 1, "The Doctor and the Public", No 5, May 12, "The Battle is Not Yet Won"

Numbers 1 and 3 were regular Bulletins, numbers 2 4, and 5, "Spot" Bulletins the distinction being that the latter have a timely and immediate usefulness in a higher degree than the usual bulletins

It is planned by the use of this method of presentation to emphasize one subject at a time, taking advantage of current popular thinking to present our ideas at the time they will receive the most widespread acceptance. Thus is avoided the academic attitude of indifference to timely current events while at the same time nothing in educational value is lost

The function of these bulletins may be indicated by quoting from the explanatory description printed on the cover of each issue

"Physicians as a class are more influential in their communities than any other group. They have little time to address themselves to the technique of utilizing their influence. This service will aim to offer concrete, specific suggestions to make it more easily possible for the doctor to exert the power of moulding public opinion which he already possesses

"The service will provide

"1 Subjects for talks before groups or over radio, with outline of speeches, and sample completed talks

"2 Ideas and suggestions for developing local speaker's bureaus in county medical societies, practical hints on speaking in public, timely topics which will interest certain groups on special occasions

"3 Suggestions for assisting the doctor in appropriately commenting on quasi-medical matters of timely public interest in the course of his usual day to day contacts at club church or elsewhere."

Reprints were obtained of the article in the May issue of *Nation's Business* entitled "Uncle

Sam, M D" They were sent to the 23,000 names on the mailing list of important influential citizens which we have built during the course of the last year and a half, and which now represents a considerable financial investment. We were requested to supply to two other state societies copies of this reprint in quantity bearing the imprint of the other societies, these were furnished to the number of 9,000 and additional requests are expected.

In all, as of the date of this supplementary report, a total of 95,994 copies of the pamphlet "On the Witness Stand" have been sold to medical societies and individuals. This document shows a clear profit over all costs of preparation and printing, besides supplying for our own use without cost 24,006 copies, 16,800 of which are now on hand. The medical society of one state where the danger of the passage of a health insurance law was great, purchased a total of 36,000 copies. In all, 120,000 copies were printed of this document.

Work is now under way on a popular pamphlet to be entitled, "What It Means to be a Doctor." It is believed that to combat cultism with mere opposition to its false claims is a weaker approach to influencing public opinion than to build up among the people an increased understanding of the skill and experience which the physician has to offer the public—what it means to be a doctor—presenting the facts in an interesting and persuasive narrative style which will engage and hold the attention of all classes of readers. The manuscript of this document will be written by Mr Dwight Anderson, Director of the Public Relations Bureau of the Society. The printed pamphlet will be available for distribution early in the fall of 1937.

Since our report was rendered, the director of the bureau has attended standing committee meetings of the society and two meetings of a special group engaged in informal discussions with members of the Committee on Medical Jurisprudence of the Association of the Bar, he has made three trips to Rochester in connection with preparations for the annual meeting of the Society.

Reprints of Dr Winslow's article "The Best Doctor" and examples of our current popular pneumonia publicity have been mailed to our entire list of names. The usual advance releases to newspapers have gone out in connection with the annual meeting of the Society.

(Referred to the Committee on Report of Committee on Medical Trends)

13 Supplementary Report of the Committee on Economics

Section 68

DR. FREDERIC E. ELLIOTT, *Kings*. At the March meeting of the Executive Committee we presented for their attention a magazine called "The New York Woman" in which there appeared an article entitled "Babies C O D"

The very obvious purpose to prejudice public opinion against the private practice of medicine is evidenced by the alleged fees which are being charged. This exhibit is for the Reference Committee, and I have not read it in its entirety other than one or two items "The Specialist's Fees, \$5,000," and so forth.

Page 31 of this same issue contains a second article complementary to the c. o. d. article, and this was entitled "Where to have a baby in New York," and there are listed some sixteen of our outstanding institutions with their bill-of-fare of prices, and in this article it is made evident that these institutions are offering flat-rate fees for hospital care, which includes the services of a doctor.

In a subsequent issue of this same magazine appears an article "The Luxury of Illness," in which we are informed of the inevitable trend toward the absorption of the medical care of the patient by a State Department, State doctors.

Under the instruction of the Executive Committee, the Economics Committee made an investigation as to the source of this material and we have first-hand knowledge that it was written by a staff writer of this magazine from material provided to them by the United Hospital Associates of New York, and supporting that is a communication on the letterhead of that organization signed by Mr Frank VanDyke, calling attention to these articles.

We then set out to obtain first-hand information. A questionnaire to each obstetrician listed in our state directory in the hospital section. We sent out 513 questionnaires. 192 physicians replied, representing 153 hospitals. It is interesting to observe that 190 hospitals are not represented on our study due to one of two things: the physicians who received these questionnaires were either indifferent to matters which seriously concern them or, as we know in some instances, were fearful of making a reply to an official committee of this society else it might bring down the displeasure of the hospital administrators on their heads.

I shall not read the tabulation of this study unless someone requests it. The significant fact borne out by these answers is that fifty per cent of the births in New York State hospitals were accomplished with no recompense whatsoever to those who were responsible for the maternity care.

We have pointed out the fact that in many of these replies the intern or resident is given a very wide latitude in judgment as to when staff members who are there only supervising their work shall be called in in the event of complication.

This Committee on Economics recognizes that it is not within our scope to consider this, but we suggest that a competent committee of the Society should give it consideration.

The answers to this questionnaire further bear testimony that much of the so-called flat-rate obstetric service might be well returned

to domiciliary care and would be returned to a source of support to the medical profession

The Committee on Economics feels that it will be of no avail to rail at the wrong in this situation nor to adopt any kind of a resolution. We feel that this challenge can only be met by the creation of a constructive program which will meet the challenge of the various groups interested because not only is this dolo of free care being permitted in this field and in others, but we feel in the interest of getting good medical care for all of the people, that this points again to the necessity of constituting ourselves such an organization that we may properly construct and advance a program which will provide good medical care to all the people with a reasonable and proper economic support for those who render that care.

THE SPEAKER Referred to the Reference Committee on Report of Committee on Economics

14 Supplementary report of Committee on Legislation

Section 69

DR. HOMER L. NELMS, *Albany* Your Legislative Committee begs leave to submit the following supplemental and final report covering our activities and recommendations for the current year

The Legislature convened on January 1 and adjourned on May 8. During this interval, approximately six thousand bills were introduced. It should be remembered that these bills are not earmarked, but it falls to the lot of Dr. Lawrence and your Committee to determine the ones that have medical or public health aspects. This done, we come to the larger responsibility of determining policy and legislative strategy

A careful survey shows that thirty-three bills were defeated which we considered detrimental to the best interests of the public and the profession. These included bills on compulsory health insurance, anti-vivisection, anti-vaccination, and the extension of osteopathic and physiotherapy practice, together with a host of other impractical proposals

Twelve of the constructive measures which received our approval have passed both Houses of the Legislature and, with one exception, are now awaiting the Governor's signature to make them law. These include provisions for the creation of a cancer commission and also a commission for the hard of hearing

Special mention should be made of Senate Bill Int. No. 838, introduced by Mr. Esquirol and known as the "Malpractice Bill," which was passed by both Houses but is not yet signed by the Governor. This bill will relieve physicians doing gratuitous work in municipally supported hospitals or sanatoriums from suits for malpractice, and in this State will have a

far-reaching effect. It is hoped that at a later time its provisions can be extended to cover all gratuitous work in charity clinics, whether municipally or privately owned

One of our greatest legislative needs is for a physicians' and surgeons' lien law for liability cases. The principle of the lien is well-established in law. The services of undertakers, lawyers, hospitals, and mechanics have all been recognized and protected by fairly effective lien laws. There is nothing in reason nor logic that should deny this same right and privilege to physicians, and, yet, for seven consecutive years the Legislature has denied us our inalienable rights under a lien law. Your Committee has made a special effort to analyze the causes back of these legislative failures. We have encountered the almost unanimous opposition of the legal profession and groups representing insurance carriers. In legislative chambers these interests are powerful. Your Committee has studied carefully all the objections offered to the various lien bills introduced through the years, together with the reactions of the Legislators to these proposals. In view of this experience, and realizing the urgent need of a physicians' and surgeons' lien bill, we make the following specific recommendation

That the Legislative Committee be authorized to negotiate and attempt to reach a mutual understanding with the proper and responsible officers of the State Bar Association, representatives of insurance carriers, and other interested groups in formulating a sound public policy, based on the principle of equal rights for all and having for its object the drafting of a physicians' and surgeons' lien bill to be presented at the next session of the State Legislature in 1938

After careful deliberation your Committee is of the unanimous opinion that this procedure is the shortest and best route to the early enactment of a lien law in this State

THE SPEAKER Referred to the Reference Committee on the Report of Committee on Legislation

15 Committee on Maternal Welfare

Section 41

DR. KOSMAK WHEREAS the constantly increasing interest in maternity by professional, lay and governmental agencies demands the cooperation of the organized medical profession in formulating plans and procedures,

Therefore be it resolved that a special committee of three members of the State Society be appointed by the incoming president each year, to be known as the Committee on Maternal Welfare to which shall be assigned the study and consideration of whatever activities are related to this field that may come within the province of the work of the State Society

THE SPEAKER Referred to Reference Committee (A)

Sam, M D" They were sent to the 23,000 names on the mailing list of important influential citizens which we have built during the course of the last year and a half, and which now represents a considerable financial investment. We were requested to supply to two other state societies copies of this reprint in quantity bearing the imprint of the other societies, these were furnished to the number of 9,000 and additional requests are expected.

In all, as of the date of this supplementary report, a total of 95,994 copies of the pamphlet "On the Witness Stand" have been sold to medical societies and individuals. This Committee on Economics recognizes that it is not within our scope to consider this, but we suggest that a competent committee of the Society should give it consideration.

The answers to this questionnaire further bear testimony that much of the so-called flat-rate obstetric service might be well returned

MINUTES OF ANNUAL MEETING

1221

21 Dismissal of Hospital Physicians Without Hearing

Section 55

DR. SIMON FRUCHT, *Kings* WHEREAS, physicians serve on hospital staffs of municipal and voluntary institutions for long years without compensation, and,

WHEREAS, these physicians oftentimes, after many years of faithful and diligent service are summarily dismissed without being granted a hearing by the Board of Directors of these institutions,

Be It Resolved, that the House of Delegates of the Medical Society of the State of New York go on record as opposed to any such dismissal on the part of the directors and boards of these institutions without a hearing

THE SPEAKER Referred to Reference Committee B

22 Recommending a Penalty for Delayed Payment of Compensation Medical Claims

Section 45

FROM WESTCHESTER COUNTY SOCIETY, WHEREAS, the 'Minimum Medical Fee Schedule for Medical treatment and care of injured employees,' as established by the State Industrial Commissioner under the Compensation Law, applying to the "Metropolitan Area," provides under line 23 that a discount of 5% may be deducted from all medical bills in amounts of \$1500 or more if paid within 30 days of receipt by the insurance carrier, and

WHEREAS, the expressed purpose of this provision is "to facilitate prompt payment of medical bills", and

WHEREAS, certain insurance carriers permit many of their uncontroverted claims to remain unpaid many months after the discount period despite the provision of Section 15-g, paragraph (1) of the Workmen's Compensation Law which states that "Unless within thirty days after a bill has been rendered to the employer such employer demands an impartial examination of the fairness of the amount claimed the amount claimed shall be deemed to be the fair value of the services rendered" and

WHEREAS, it is deemed both desirable and fair that the 5% discount for early payment should be balanced by a reasonable penalty for delayed payment, therefore

Be It Resolved, by the Medical Society of the County of Westchester, that the House of Delegates of the Medical Society of the State of New York be urged to memorialize the State Industrial Commissioner to the effect of this resolution and to request, in the name of the State Medical Society the line 23 of the "Minimum Medical Fee Schedule" be amended to provide that when compensation claim is

can Medical Association, the Radiological Society of North America, the American Roentgen Ray Society, the American College of Radiology, the American College of Surgery, the American College of Physicians, and, locally, the New York Academy of Medicine, as well as all hospitals operating throughout the country, and municipal hospitals, Federal agencies, Public Health Service and the Army and Navy,

Be It Resolved, that the Medical Society of the State of New York adopt the necessary measures to the end that the practice of radiology, comprising the practice of diagnostic and therapeutic roentgenology, including the use of radium, be recognized as a special branch of medicine.

THE SPEAKER Referred to Reference Committee D

20 Regulating Child Labor

Section 43

DR. KRELL, *Bronx* 1 WHEREAS, the several states have coped unsuccessfully for over one hundred years with the problem of regulating child labor, and have so far failed to pass uniform laws affecting such regulations,

2 WHEREAS, child labor, by reason of its cheapness is a powerful weapon in the struggle for industrial markets and therefore its tolerance in one state jeopardizes such regulations as may exist in another,

3 WHEREAS, the experience of this country with three previous attempts by the Federal Government to regulate child labor has proven the feasibility of such legislation as well as its effectiveness and unquestioned superiority over the efforts of individual states, its lack of bureaucracy and interference with individual liberty,

4 WHEREAS, with the death of the N.R.A. and consequent frustration of the last national attempt to curb child labor, the return of that evil is ever more disturbing and menacing

5 WHEREAS, we as physicians are peculiarly fitted to estimate the hazards of industrial employment upon the health and development of growing children that by reason of this knowledge, we, as physicians, should be remiss in our duties as citizens if we stood aloof and failed to urge a measure which will affect the future health of our nation,

Be It Resolved that the New York State Medical Society go on record as favoring the adoption of the Child Labor Amendment to the Constitution of the United States

And *Be It Further Resolved*, that copies of this resolution be forwarded to the Governor and Chairmen of the Senate and Assembly Judiciary Committees

THE SPEAKER Referred to Reference Committee (A.)

16 Section on Orthopedic Surgery

Section 47

DR. MASTERSON, *Kings* WHEREAS in most of the medical schools in the State of New York there is an independent chair of orthopedic surgery, and

WHEREAS, at the New York Academy of Medicine there is an independent section on Orthopedic Surgery, and

WHEREAS, there is in the State of New York a very large number of surgeons limiting their practices exclusively to orthopedic surgery, and

WHEREAS, in all of the larger cities and in many of the smaller cities in our state orthopedic surgery is definitely recognized by the profession as an independent, well-established, specialty, and

WHEREAS, the orthopedic surgeons of the State of New York take a very active part in the programs of the Orthopedic Section of the American Medical Association, the American Orthopedic Association, the American Academy of Orthopedic Surgeons and in the American Board of Orthopedic Surgery, and

WHEREAS, the orthopedic surgeons of this State have in the past participated but to a minor extent in the scientific sessions at the Annual Meetings of the New York State Medical Society,

Therefore, be it resolved that the House of Delegates approve and authorize the formation of an independent section on Orthopedic Surgery in the Medical Society of the State of New York.

THE SPEAKER Referred to Reference Committee C

17 In Memoriam—Daniel S Dougherty, M D

DR. WIGHTMAN WHEREAS, there has been removed through death, since the last meeting of this body our former esteemed and beloved secretary, Dr Daniel S Dougherty,

Be it resolved, that at this, the stated meeting of the Medical Society of the State of New York, we spread upon its minutes our tribute to Dr Dougherty

His long service was devoted to constructive thought and the strengthening of our organization He zealously and unselfishly carried on,

even with diminished strength and health, counting the welfare of the State Society above his personal good

We hereby record our testimonial and affection for his many years of devoted service.

THE SPEAKER Obviously this need not go to a reference committee.

THE SECRETARY I move that this be spread upon the minutes and a copy sent to the family (Motion seconded and carried)

18 State Medicine

Section 52

DR. KRELL, *Bronx* WHEREAS, the NEW YORK STATE JOURNAL OF MEDICINE in a leading editorial of May 15, 1937 acknowledges the existence of State Medicine in a limited form, and

WHEREAS, the same editorial ventures the prediction that the trend for state medicine, if left unguided, will, by a series of progressive encroachments, completely displace private practice, and

WHEREAS, it is the opinion of organized medicine, as expressed in the above-named editorial, that the medical profession should assume leadership in that movement with a view to obviating any injustice that might be suffered by the profession or by the public through precipitate action,

Therefore, be it resolved, that the Speaker of the House of Delegates be authorized and instructed to appoint a committee at this session for the immediate study of this question, and

Be it further resolved, that this committee shall report from time to time its findings in the STATE JOURNAL, and

Be it further resolved, that no definite recommendation of this committee shall be acted upon by the State Society without first submitting the question to a referendum of the entire membership of the State Society

THE SPEAKER I am willing to send this resolution to Reference Committee B, but with the understanding that I declare out of order the recommendation that the Speaker shall appoint any committee that has a continuing action, because that is contrary to our constitution and by-laws. Appointments to continuing committees reside in the president and not in the speaker. That being understood, the matter is referred to Reference Committee B

19 Radiology

Section 71

DR. KOVACS, *New York* WHEREAS, the practice of roentgenology, entailing the utilization of chemicals and armamentaria for the production of electro-magnetic waves for diagnostic and therapeutic purposes, is recognized as a special branch of medicine by the Ameri-

MINUTES OF ANNUAL MEETING

1223

profession is ready to aid them in health as well as in disease,

(Inform the Public)

Therefore, *Be It Resolved*, (1) That each physician and every association of organized medicine be called upon to renew their efforts to inform the public of the need for personal preventive medicine and the benefits that may be derived therefrom

(Aid the physician)

Be It Resolved, that (2) the medical profession take energetic steps to assemble the whole resources of the medical and social sciences in personal preventive medicine and to place them at the disposal of the family physician, thus to strengthen him anew in understanding and helpful aid in the problems of life and living, and personal prevention of illness

(Physician's Service is Basic)

Be It Further Resolved that, each physician and every association of organized medicine be called upon to seek ways to give service to all worthy welfare, social and educational organizations, which may be of aid in personal preventive medicine, especially in making his basic health examination reports available (with discretion) for use in school, camp, settlement athletics and other kindred fields where, under socialized conditions, health examinations are now being conducted under conditions less advantageous than in the office of the family physician.

(Uninterrupted Service through life)

Be It Further Resolved, that all physicians and every association of organized medicine be called upon for medical guidance and health promotion throughout the lives of the individuals and families under their care. This will provide a continuing medical service and a continuing medical record, to the end that every one may be better served in his own lifetime and future generations may profit by the accumulation of the scientific record of whole lives

THE SPEAKER Referred to Reference Committee B

26 Socialized Medicine

Section 46

DR. FISCHOFF, *Kings* WHEREAS, the remarkable progress and achievements of modern scientific medicine and modern medical education make possible medical facilities and personnel sufficient and competent to provide adequate care in health, illness and disability for all our people, and

WHEREAS, despite this medical science, facilities and personnel, millions of the people still receive inadequate medical care, and frequently no such care at all, while, at the same time, tens of thousands of our doctors and associated

workers are insufficiently employed in their calling and insufficiently remunerated for the professional services rendered by them, and

WHEREAS, the fundamental cause of this public and professional state of affairs is caused by the inability of most of our people to purchase adequate or any medical care for themselves, and primarily due to the private individual or institutional method of rendering medical care on a commodity or fee-for-service basis, and

WHEREAS, the people's health is essentially the people's concern, not less important than education, property protection, or any other public service, and therefore fundamentally is a social or state interest and obligation, no longer to be left to the economic and medical uncertainties of our mercantile methods of securing or providing medical care, with all the evils that necessarily follow therefrom,

Be It Therefore Resolved by this House of Delegates that we approve the reorganization of medical care and practice so as to provide all the medical care needed by our people, and so as to realize in full the true functions and purposes of medical science and art, at the same time assuring to the medical profession and the allied workers concerned in medical care with economic security and adequate conditions needed for the proper pursuit of their professions and

Be It Further Resolved that we endorse the following plan as a suggestive basis for such medical reorganization and for appropriate legislation

Program

1 Adequate medical care of the sick and injured as a social function right and duty, and not as a private or public charity Curative as well as preventive means, measures and agencies to be included

2 A socialized system of medical care in health, illness and injury free of fees

(a) Under the auspices and with the subsidy of the state

(b) Financed by taxation, similar to the public educational system or other governmental functions

(c) Operated and regulated by the organized medical and allied professions, the medical and dental colleges, and the officials of existing public health agencies

(d) This system to include all dental, pharmaceutical nursing and allied services, and personnel

3 All hospitals clinics laboratories, pharmacies, etc to be publicly owned and operated institutions accessible to the sick free of charge The hospitals and clinics to be the medical centers for ward and ambulatory cases, and to be properly organized coordinated, and geographically distributed. House sick calls to be received at these centers and to be assigned to local or neighborhood physicians designated to cover specific local territories

neither paid with discount nor controverted within 30 days, a cumulative penalty of 1% per month shall be added to the face amount of the claim as rendered until full settlement has been made

THE SPEAKER Referred to Reference Committee (C)

23 Employment of salaried physicians on contract by municipalities for medical service to home relief clients

Section 74

FROM WESTCHESTER COUNTY SOCIETY

WHEREAS, there is a strong tendency among public officials and welfare officers to favor the employment of physicians on salary to render medical service to welfare clients rather than to permit the patient to be attended by the physician of his choice with payment of the physician on a fee-for-service basis, and

WHEREAS, this manner of providing medical relief makes medical service for the poor a distinctly separate type of service from that available for those who are self-sustaining, constituting an intolerable discrimination against the unfortunate poor and denying them their elementary American right to choose their own medical attendants, and

WHEREAS, such economies as may be claimed to result from such a contract system of medical relief are made possible only by exploitation of the physicians in a manner that must inevitably produce a sub-standard quality of service, and

WHEREAS, physicians serving under such contract systems are clearly violating the Principle of Medical Ethics of the American Medical Association which forbid contracts where "free choice of a physician is prevented", where "compensation is inadequate to assure good medical service", or where "there is interference with reasonable competition in a community", now,

Therefore, *Be It Resolved*, that the Medical Society of the County of Westchester does hereby recommend that the Medical Society of the State of New York condemn the employment by municipalities of physicians on salary to attend home relief clients, and that the State Society sponsor legislation to amend section 84 of the Public Welfare Law in such a way as to require that medical relief be furnished by the physician of choice and compensated on a fee-for-service basis and to delete the present section enabling medical relief service by contract, and

Be It Further Resolved, that the Medical Society of the State of New York sponsor such legislation as may be necessary to establish control over the medical aspects of medical relief service in the same way as the medical aspects of Workmen's Compensation Service are controlled

THE SPEAKER Referred to Reference Committee D

24 Recommending a memorial to the American Medical Association urging a New Policy for Medical Publicity

Section 75

FROM WESTCHESTER COUNTY SOCIETY

WHEREAS, proponents of compulsory health insurance are making every effort to create a public demand for its establishment in the United States, and

WHEREAS, the general public throughout the United States is almost completely uninformed regarding the financial costs of such an experiment, the inevitable effects of such legislation upon the quality of medical care, and the psychological and technical obstacles which almost certainly would render compulsory health insurance deleterious to health and unsound as insurance, and

WHEREAS, the facts concerning the economic and psychological foundations of quality in medical practice and a realization of the vital public interest in the preservation of these foundations must be widely publicized to the laity, therefore

Be It Resolved, that the Medical Society of the County of Westchester does hereby memorialize the Medical Society of the State of New York, recommending that it in turn immediately and urgently memorialize the American Medical Association, recommending that the American Medical Association establish a Department of Public Relations whose function it shall be to engage the most expert and talented professional public relations counsel available, this Department of Public Relations to be equipped at once with adequate financial resources to carry on a permanent campaign of publicity and advertising through the most obvious media reaching the masses of public opinion and setting forth dramatically and accurately, the story of medical progress in the United States, revealing and explaining the foundations of future progress and creating an informed public will to preserve those foundations, and

Be It Further Resolved, that this resolution be introduced in the House of Delegates of the Medical Society of the State of New York at the meeting of the House, May 24, 1937

THE SPEAKER Referred to Reference Committee A

25 Preventive Medicine

Section 53

Resolution presented by the Medical Society of New York County

(Personal Preventive Medicine)

WHEREAS, many lives are lost and many persons suffer needless illness, because the public does not sufficiently understand that the medical

MINUTES OF ANNUAL MEETING

1225

WHEREAS, there is no justification, social, ethical or professional, for this economic discrimination against the physicians who constitute a most important part of such personnel,

Be It Therefore Resolved, by this House of Delegates that it hereby record itself in favor of compensation for all medical services rendered in all medical institutions of the State of New York, whether public or voluntary, and the officers of this society make every effort to support the movement to make pay for professional work a legal and practical reality

THE SECRETARY In the Executive Committee's report, before its proper reference committee, is a definite suggestion toward the same end.

THE SPEAKER I am willing to refer this communication to the Committee of Reference acting on the Executive Committee's Report. This is not a resolution which could ordinarily be accepted here.

Referred to Reference Committee A.

29 Opposition to enactment of compulsory health insurance law

THE SECRETARY This resolution was accompanied by a letter stating "By the action of the Society, our delegates were instructed to present this resolution", this is from the Medical Society of the County of Albany

WHEREAS, The Medical Society of the State of New York has always opposed the enactment of any compulsory health insurance law, and

WHEREAS it is a recognized fact that most States or countries having compulsory health insurance began by promoting voluntary insurance or indemnity schemes, and

WHEREAS, there has been a bill before the Legislature providing legislation that would enable the creation of medical indemnity insurance organizations,

Be It Therefore Resolved, that the Medical Society of the State of New York maintain its position of opposition to all schemes of this character unless a decision to the contrary is reached in the House of Delegates' meeting either in regular or special session.

THE SPEAKER Referred to Reference Committee B

30 Automobile License Plates

Section 76

DR. VICKERS, *Washington* WHEREAS, it is the policy of the Motor Vehicle Department of the State of New York to issue distinctive license plates to members of various fraternal, social and civic groups, as may be noted by the numerous plates seen with different combina-

tions of letters before the numbers, as ST-, AL-, QS-, AY-, and others, and

WHEREAS, there are registered, as members of the Medical Society of the State of New York, the total of 14,194 physicians for the year 1936

Therefore, Be It Resolved, that the Medical Society of the State of New York petition the Motor Vehicle Department of the State of New York to issue special and distinctive license plates to physicians in good standing and registered with the Medical Society of the State of New York, these plates to bear the letters "MD", or "DR", followed by the proper numbers, and

Be It Further Resolved, that no more than one set of license plates bearing these letters shall be issued to one physician and that for use on his professional car, and

Be It Further Resolved, that the application for special plates shall be approved by the Secretary of the County Medical Society of which the applicant is a member

THE SPEAKER Referred to Reference Committee D

31 Establishment of a Section on Pathology

Section 60

THE SPEAKER The following resolution was presented by the Special Committee on Clinical and Pathological Laboratories, and approved by the Committee Minora, April 12, 1937

It is recommended that the Medical Society of the County of New York instruct its delegates to support the resolution for the establishment of a section on pathology of the Medical Society of the State of New York.

THE SPEAKER This will be referred to the Committee on Council Report. We will now declare a recess The House will reconvene at 2 P M

AFTERNOON SESSION

The meeting was called to order by the Speaker at 2 P M

32 National Public Health Policy

Section 38

THE SPEAKER The chair recognizes Dr Booth For your information gentlemen, this is a special committee appointed by President Winslow to make certain recommendations The Committee has met a number of times and Dr Booth as chairman of the Committee, is again reporting

Dr Booth *Elmira* The Special Committee appointed by President Winslow to consider Provision of Medical Care begs to submit the following report

4 All equipment, supplies, laboratory, and other facilities of a medical, surgical, dental, pharmaceutical, nursing or other nature, to be furnished free by the state

5 All medical, dental, pharmaceutical, nursing and allied education to be furnished free by the state.

6 All duly licensed or registered physicians, dentists, druggists, nurses, etc., to be legally entitled to practice under the system as full time practitioners or workers

(a) Subject to established rules and regulations of admission and practice.

(b) Proper safeguards of their rights and privileges under the system and the law

(c) With representation and a voice in the operation of the system

7 Compensation to be adequate and on a salaried basis

(a) Graded according to time of graduation, length of service in the system, rank held, and type of work.

(b) Salary increases and promotion to higher ranks to be based on similar considerations and to be automatically enforced

(c) Pensions, sickness, old age and other disability and social insurance to be included and applied

8 Hours of work to be assigned and regulated and scheduled so as to provide

(a) Adequate medical care for the sick and injured at all times

(b) Adequate time and opportunity for the physicians and allied workers for rest, recreation, vacations, and further professional study—with pay

9 Organized cooperative groups and group methods to be employed under the system wherever possible. Special provisions to be made for rural and other territories inaccessible to regularly organized medical centers

10 Individual private medical practice permissible under the same conditions and regulations as in private education, plus existing licenses and requirements by the state.

THE SPEAKER Referred to Reference Committee C

27 Plans for Medical Care

Section 48

DR. DAVIDSON, *Kings* WHEREAS, in the past ten years, repeated investigations have been made in this country of medical conditions, of methods of providing medical care to our people, and of methods of medical practice, to wit the investigations and reports of the Committee on the Costs of Medical Care, the 1931 Report of the Special Health Commission of New York State, the Legislative Investigation of California, the joint investigation of the Michigan State Medical Society and the Legislature of the State of Michigan, the latest New York Hospital Survey, the Report of the studies

on American Medicine made by the American Foundation for Studies in Government, and

WHEREAS, all these investigations and reports, as well as other similar studies, regardless of their differences in objectives and methods of approach and in their conclusions and recommendations, have definitely agreed on the inadequacy of medical care provided, both in quantity and quality, and have definitely indicated the urgent need for some sort of change in our present medical system, and

WHEREAS, these reports have also disclosed the highly unsatisfactory economic status of a large proportion of the professions engaged in the medical and allied services, and equally unsatisfactory professional conditions which menace these professions and which in turn react on the medical care which our people need and expect, and

WHEREAS, organized medicine of New York State has to date not been able to advance any satisfactory plan for the solution of this medical problem, so serious to both the people and the professions alike,

Be It Therefore Resolved by this House of Delegates that the president of this Society shall appoint a special committee, broadly representative of the various trends and schools of thought on this supreme medical problem, to study and report upon these various investigations and reports aforementioned, and to invite and hear the expression of opinion of all groups interested in these problems, and to give a full report on a complete and accurate study of the three definite proposals before the public and the profession for the approach to, or the solution of the medical situation, to wit voluntary group and insurance plans, compulsory health insurance, and public medicine—all this with a view to the development of a sound plan of making proper medical care available to the people of this state.

THE SPEAKER This is not a resolution presented by Kings County. It is a resolution presented by the gentleman who so eloquently spoke just now. I will refer it to Reference Committee C.

28 Compensation for Professional Services

Section 42

DR. DAVIDSON, *Kings* WHEREAS, the burden of medical charity has grown to proportions far beyond the ability of the medical profession to carry it any longer, and

WHEREAS, this burden of medical charity is the proper concern of the whole community and government, local and state, and not alone of any particular class or professional group, and

WHEREAS, the entire personnel involved in the administration and service of medical charity is, and has always been, compensated for their services, with the only exception of the medical professional staffs, and

specific field. The nominations of these "experts" should be by units of organized medicine. The nominations and recommendations by organized medicine should be given preferential consideration by Government in making its selection."

8 That the adequate administration and supervision of the health functions of the Government, as implied in the above Proposals, necessitate in our opinion a functional consolidation and all federal health and medical activities, under a separate department.

* * *

We, who subscribe to the above principles, proposals and recommendations held the view that compulsory health insurance does not offer a satisfactory solution on the basis of these principles and proposals and repeat our objections to its enactment in this country

Your Committee recommends the adoption by the House of Delegates of the above, and

Further recommends to the House of Delegates that it authorize the creation of a Committee to confer with Government Agencies and other organized medical groups so that differences in conception, definition of terms and applicability of principles and procedures may be ironed out in conference. This committee shall function for matters concerning the State of New York.

We further recommend that the House of Delegates of the American Medical Association be asked by our Delegates to create a similar committee to act nationally

THE SPEAKER Referred to Reference Committee B

33 Report of Reference Committee on the Reports of the Treasurer and Trustees

Section 8

DR. TOWNSEND Your Reference Committee on the reports of the Treasurer and Trustees has reviewed in detail the report of the Treasurer and notes with gratification the increased income from membership dues of \$3,373, and the increase of approximately \$6,600 in income from investment, a total gain over 1935 of \$10,000 00

However, this prosperity is not without pain, since his report shows a loss of \$4,220 00 in defaulted bond coupons and probably a material loss on bonds whose par value was \$23,000 00. Furthermore, the reports show that \$33,000 00 of our funds rests in savings banks at a low interest rate and \$50,000 00 is invested in high-grade shares. These shares have increased

in value \$1,910 00 whilst our bond holdings have depreciated \$3,614 00 making us the poorer by \$1,700 00

We commend the treasurer in his cautious attitude until the trend of trust investments is more clearly marked

In his supplementary report the treasurer, calling attention to the small margin between income and expenditure, states as follows "One of the ways to solve the situation is to scale down on expenditures by whatever laudable efforts your officers and delegates may find it possible to employ. Another is to increase the Society's membership and the final and least desirable is to levy an additional assessment. The latter should only be regarded in the light of a final resort. Your Committee on Reference concurs in these opinions and suggestions

The Report of the Board of Trustees is worthy of careful reading by each member of the Society. It calls attention to (1) the increasing difficulties of investing and re-investing, (2) to the lowered rate of income from our funds, (3) to the increase of thirty per cent in expenditures as against but ten per cent increase in income during the past eight years, and (4) the necessity of all committees keeping within their budgetary allowance. The Trustees advise careful scrutiny of all actual or potential values which the Society receives or may receive for each dollar spent with which advice your Committee on Reference heartily concurs

The one recommendation offered by the Trustees has the hearty support of your Committee on Reference, to wit—that "The House of Delegates direct that the Society maintain its expenditures within its ordinary income exclusive of the principal or income from its investments and that this policy be not departed from except by resolution of the House either in regular or special meeting assembled or by reference vote"

I move the adoption of this report
(Motion seconded and carried)

34 Medical Assistance in the promotion and administration of the Motor Vehicle Laws

Section 44

THE SECRETARY The following is a resolution presented by the Genesee County Medical Society

WHEREAS there is annually reported an increase in automobile fatalities by the Department of Motor Vehicles, and

WHEREAS the physicians of the State are actively interested in preventing deaths from disease and injury,

Be It Therefore Resolved, that we take such steps as may be necessary or desirable to assist the proper state authorities, with medical assistance, in the promotion and administration of the Motor Vehicle Laws

Principles

1 That the health of the people is a direct concern of the Government, and a national health policy, directed toward all groups of the population, should be formulated.

"a. In the formulation of such policy the opinions and suggestions of organized medicine should be given preference."

"b We recommend in line with the above principle that the Medical Society of the State of New York appoint a group to formulate the principles and proposals for a State Health Policy, and we also recommend that the Medical Society of the State of New York urge the House of Delegates of the American Medical Association to create a group which shall formulate the principles and proposals of a National Health policy to be submitted to the Government."

2 That adequate medical care is an essential element of public health, and local, state and federal governments need to supplement present efforts of the medical profession in providing it.

"a. We recommend to the Medical Society of the State of New York that a Committee approved by the Council present a definition of the term "adequate medical care" for adoption by the House of Delegates, which shall be a "yard stick" in its use for all purposes connected with matters dealing with medical care, etc, henceforth"

"b That the House of Delegates of the Medical Society of the State of New York recommend to the House of Delegates of the American Medical Association the establishment of a working definition of the term "adequate medical care", suitable for the purpose of discussing national legislation and social legislation

3 That the problem of economic need and the problem of providing adequate medical care are not identical and may require different approaches for their solution.

Your Committee understands principle No 3 to imply the following

"That the problem of providing the individual with the means for securing medical care—that is the economic needs—and the problem of distributing medical services are not identical, that these problems of economic needs should be approached separately from those of distributing medical services to the people"

Proposals

1 That the first necessary steps toward the realization of the above principles is to minimize the risk of illness by increasing preventive efforts through extension of public health services, federal, state and local

"That the extension of federal, state and local preventive health measures is approved pro-

vided it meets the needs of a given situation in the opinion of the medical profession in the locality affected, and provided it integrates to the greatest possible extent the private practitioner of medicine in the development of preventive health service."

2 That an immediate problem is provision of adequate medical care for the medically indigent, the cost to be met from public funds (This is in line with the provisions of the Booth Report of 1933)

3 That public funds should be made available for the support of medical education and for studies, investigations and procedures for raising the standards of medical practice. If this is not provided for, the provision of adequate medical care may prove impossible

4 That public funds should be available for medical research as essential for high standards of practice in both preventive and curative medicine

5 That public funds should be made available to hospitals that render service to the medically indigent and for laboratory diagnostic and consultative services

With the provision—

That these consultative and laboratory diagnostic services shall be established only in regions where the medical profession approves the need of same, and after consultation with the local medical profession in the area affected"

6 That in the allocation of public funds, existing private institutions should be utilized to the largest possible extent and receive support as long as their service is in accord with the above proposals

"a That so far as the allocation of funds is concerned for these institutions, they should not be on a pro rata population basis, but should be limited strictly by the needs of given institutions in specified localities, and the allocation should have the approval of the medical profession in the locality in which the institutions are located"

"b That in the section of existing institutions to which public funds may be allocated, their rating and their needs shall be measured by the standards of the Council of Medical Education and Hospitals of the American Medical Association and that no public funds should be made available to existing institutions against and contrary to the majority opinion of the medical profession in the locality in which they exist."

7 That the investigation and planning of the measures proposed and their ultimate direction should be assigned to experts

"a It is recommended that the various subdivisions of the American Medical Association, namely, its national state and county components furnish to the Government upon request lists of experts in their communities to carry out their principles and proposals"

"b We regard the word "expert" to mean a man especially qualified by experience in his

risk of illness by increasing preventative efforts through the extension of public health service, federal, state, and local.

And that the extension of federal, state, and local preventative health measures is approved provided it meets the needs of a given situation in the opinion of the medical profession in the locality affected.

And provided that it integrates towards the greatest possible extent the private practitioner of medicine in the development of preventative health service

And that in the allocation of funds for any purpose in any localities the approval of the local medical profession be required. The reference committee approves and emphasizes the principles that the problem of economic needs and the problem of providing medical care are not identical and should be approached separately.

Your reference committee endorses and approves the proposal that the adequate administration and supervision of the health functions of the government as implied in the report of the special committee necessitating functional consolidation of all federal health and medical activities under a separate department.

And that the head of such department should be a doctor of medicine having the approval of the medical profession of the United States

Your reference committee recommends that a committee be appointed by the president of the Medical Society of the State of New York to formulate the principles and problems for a state health policy

For the establishment of a working definition of the term "adequate medical care."

And for the purposes of conferring with the government agencies and other organized medical groups so that differences in conception of definition of terms and applicability of principles and procedures may be ironed out in conference. This committee shall function for needs concerning the State of New York.

It further recommends that the Medical Society of the State of New York urge the House of Delegates of the American Medical Association to create a group which shall formulate the principles and problems of a medical health policy to be submitted to the government.

And that the American Medical Association establish a working definition of the term "adequate medical care" suitable for the purposes of discussing medical and social legislation

I move the adoption of this report.

(Motion seconded and carried)

39 Report of the Reference Committee on the report of the Committee on Arrangements and on the report of the Committee on Scientific Work

Dr. HEYL Mr Speaker and members of the House of Delegates, gentlemen

Your Reference Committee on the report of the Committee on Arrangements and on the report of the Committee on Scientific Work, annually strives in the unique function of con-

densing for you that prophecy of the adverbs, what, where, and how. The scientific program, its location and manner of execution, are necessarily fulfilled in the potential and static state long before this body convenes. For a moment now these factors are fused in ascent expectancy, and in another moment they will be released in active fulfillment. Who now could or would wish to alter that which is in the process of transpiring?

The Committee on Arrangements proclaims the welcome of the Medical Society of the County of Monroe, the Rochester Academy of Medicine, and the City of Rochester. It has provided this Chamber of Commerce Building for all sessions and exhibits, has arranged for a public meeting at the Eastman Theatre through the courtesy of the University of Rochester, the program of which concerns "The Relation of Photography and Motion Pictures to the Science and Practice of Medicine", and as an added fourth day attraction, has planned play at golf for those interested, and for the others, relaxation in visits to the Research Laboratories of the University of Rochester Medical School, or the manufacturing plants creating scientific instruments and other interesting or valuable products

The Committee on Arrangements has not forgotten the ladies and has depended on the Ladies Entertainment Committee to provide hospitality and pleasure appropriate for them. Through the Banquet Committee they will endeavor in this building on Tuesday evening to nourish our minds and bodies with instruction, food, and entertainment.

The Hotel Committee "stands ready to give assistance to those who are not able to secure adequate accommodations." They "promise to leave nothing undone that will contribute to the enjoyment of their guests." The Chairman of this Committee on Arrangements, Dr. Leo F. Simpson, most concisely summarizes his report in these words: "We know that the State Society commands your loyalty, the scientific program and exhibits will deserve your attention, and certainly the Fourth Day of relaxation will bring joy to the hearts of all who participate."

Dr. William A. Groat, Chairman of the Committee on Scientific Work, comments on the unusual merit and balanced character of the various section subjects for presentation, commends the Committee on Arrangements for their centralization of all activities, states why, on account of limited space, the scientific exhibit is being largely provided by the University of Rochester School of Medicine and Dentistry, pays tribute to Dr. Clarence V. Costello, in charge of all scientific exhibits, and to Dr. John Henderson of the Advisory Committee on Exhibits for his able and detailed assistance relative to the Motion Picture display. Dr. Groat also acknowledges the work of Dean George H. Whipple for the symposium on "The Blood" and the help of Dr. Byron Stookey in arranging the symposium on "The Relief of Intractable Pain."

THE SPEAKER Referred to Reference Committee A

35 Greetings from New York State Hospital Assn

THE SECRETARY We have a letter from the Hospital Association of New York State transmitting a copy of a resolution unanimously adopted at the 13th Annual Convention of the Hospital Association of New York State

The resolution is as follows

WHEREAS, Dr Floyd Winslow, as president of the Medical Society of the State of New York, together with his Public Relations Committee has met with the Public Relations Committee of the Hospital Association of New York State on various occasions during the past year to consider hospital-physician relationships and in such meetings, as well as through other contacts has evidenced an extremely cooperative and understanding approach to these matters resulting in great progress toward the promotion of better relationship between the two groups,

Be It Resolved, that the Hospital Association of New York State in annual meeting assembled extend to Dr Winslow and his committee members, our greetings and sincere thanks while at the same time expressing the hope that this splendid work, so ably begun, be continued with unabated interest and endeavor through the coming years

THE SPEAKER No action is necessary It is a matter of record.

36 Applications for retirement

DR. BEDELL The names have already been printed. I move that the retirements be granted

THE SPEAKER The names have already been published The motion is before you

37 Revision of Constitution and By-Laws

Secretarial Notice Minutes of action by the House of Delegates on amendments submitted by the Committee on Revision of the Constitution and By-Laws will appear in the next issue of the NEW YORK STATE JOURNAL OF MEDICINE (July 15) as Section 37 of the minutes

PETER IRVING, Secretary

38 Report of Reference Committee B on report of Special Committee to consider provision of Medical Care

Section 32

DR. MCGOLDRICK Your Reference Committee endorses the report of the special committee to consider the provision of medical care. The principles and proposals therein laid down should afford a good working basis towards the accomplishments in mind. Your reference committee will especially emphasize the proposal that the first necessary step towards the realization of the principles given is to minimize the

to the community, your committee recommends that at the time of discharge of such a patient it be made mandatory for state institutions to forward a report to the family physician, or the committing examiners

I move the adoption of this recommendation
(Motion seconded and carried)

Regarding the proposed revision of rules of the State Welfare Governing Dispensaries, your committee feels that in view of the fact that corrective legislation has been unsuccessful during the past year, and in view of the fact that there are matters still under consideration, no action can be taken at this time, but this committee recommends that further study and continued efforts be made through the proper channels to institute fair and just legislation to correct dispensary abuses

I move the adoption of this recommendation
(Motion seconded and carried.)

With reference to the deaf and hard-of-hearing, your committee commends the work that has been done during the past year for these cases, and recommends continued effort in this direction.

I move the adoption of this recommendation.
(Motion seconded and carried.)

With regard to motor vehicle accidents In view of the splendid work which is being done by the National Safety Council under the presidency of Dr Cassius Watson, a member of the State Society and Chairman of the Section on Industrial Medicine and Surgery, your committee recommends that the wisdom included in the comments and observations of the Public Relations Committee be transmitted to the National Safety Council

I move the adoption of this recommendation
(Motion seconded and carried.)

Legislation to care for cancer patients The report of the Committee on Public Relations is informative in character, and your committee approves the suggestion that a commission be appointed to supervise the carrying out of the necessary details

In conclusion your committee wishes to commend to the House of Delegates the memorial to Dr Luther Warren as published in the report of the Committee on Public Relations

In Memoriam

The Public Relations Committee of the Medical Society of the State of New York wishes to express its profound sympathy on the death of Dr Luther Fiske Warren who died in Brooklyn January 18, 1937 Dr Warren was the immediate past chairman of the Public Relations Committee, and gave unsparingly of his time and talents to further better relations between the Medical Society and other organizations working in the field of preventive and curative medicine. A former president of the Medical Society of Kings County, he was physician-in-chief of the Long Island College Hospital and St. John's Hospital, medical direc-

tor of the Brooklyn Home for Consumptives, and consulting physician at Methodist Episcopal Hospital, and Lutheran Hospital, Harbor Hospital, Brunswick General Hospital, and Coney Island Hospital He was professor of Medicine at Long Island College of Medicine and chairman of the Board of Medical Examiners of the Regents of New York State He was intensely devoted to his work and his family He was a great man not only in his professional career as a physician, but in all the activities of his busy and useful life. By those who knew him best through years of intimate association, he was classed as a man of extraordinary brain power and strength of character His death is a great loss to his family, to the city in which he lived, to the institutions he served so faithfully, and to the Medical Society of the State of New York.

I move you the adoption of this report as a whole, as amended

(Motion seconded and carried)

41 Report of Reference Committee on New Business A, on Resolution of Committee on Maternal Welfare

Section 15

DR. CUNNIFFE Resolution introduced by the House of Delegates by Dr George W Kosmak.

"Therefore, Be It Resolved that a special committee of three members of the State Society be appointed by the incoming president each year, to be known as the Committee on Maternal Welfare, to which shall be assigned the study and consideration of whatever activities are related to this field that may come within the province of the work of the State Society"

This reference committee approves the purpose of the resolution as offered by Dr Kosmak, but feels that this work is part of the general health program, and that the work should be done in conjunction with the activities of the Committee on Public Health and Education.

We therefore, offer as a substitute resolution, the appointment of a special committee by the president, consisting of three members of the State Society, who shall formulate plans and procedures and study all activities which are related in the advancement of maternal welfare, and shall report their findings to the Committee on Public Health and Education, who in turn shall report to the House of Delegates at the next annual meeting of the New York State Medical Society

Your Committee moves the adoption of this report

THE SPEAKER The Reference Committee presents a substitute before you and moves its adoption

(Motion seconded and carried)

THE SPEAKER The substitute resolution is carried and the original resolutions are not

The Committee on Scientific Work particularly acknowledges its indebtedness to the "President of the Society, Dr Floyd S Winslow, for his invaluable assistance and remarkable ability to pour out the resources of his home City toward the making of a grand meeting." This Committee, remaining true to its scientific function, avoided even the mention of golf when it related the Fourth Day recreational program.

Mr Speaker, this Reference Committee has read the program, has visualized the sight of its enactment and realizes the intricacy and immensity of the work of these Committees in behalf of the Members of the Medical Society of the State of New York.

I, therefore, move the adoption of the foregoing report.

(Motion seconded and carried.)

40 Report of the Reference Committee on the report of the Committee on Public Relations

DR HAMMOND The Reference Committee on the report of the Committee on Public Relations has made a careful examination of the Committee's Report, and wishes to congratulate them for the constructive work which they have accomplished during the past year.

Relative to the report on the care of children with defective eyesight, your Reference Committee states that this matter has been under consideration for the past two years. You will note that the Committee on Public Relations has again recommended that where diseased conditions exist they are a matter for the medical specialist, and that a change in the law is advisable by an amendment whereby any child whose central visual acuity cannot be corrected better than 20-30 by lenses should be referred to a duly licensed physician for examination and treatment.

Inasmuch as this committee feels that this subject is highly controversial, even in the field of ophthalmology, it is recommended that a competent committee of ophthalmologists be appointed to study this question and report back at the next meeting of the society.

I move the adoption of this recommendation.

(Motion seconded and carried.)

With respect to the formation of community health relations councils, inasmuch as many of the public health relations councils are being controlled by laymen, your committee is heartily in accord with the committee's opinion and we recommend that the governing element of these agencies should take its source from the local County Medical Society.

I move the adoption of this recommendation.

(Motion seconded and carried.)

In regard to the joint meeting of legal and medical professions, your Committee recommends that each County Society arrange for one meeting a year with the members of the legal profession of that county and we urge the adoption of this recommendation.

A study of the relationship between the Grievance Committee, Legal Department of the State Medical Society, and the Public Relations Committee reveals that the most fertile field for the instigation of malpractice suits is the careless and inadvertent remarks which are made by members of the medical profession. Your committee recommends that this conclusion be brought to the attention of every member of this Society.

I move the adoption of this recommendation.

(Motion seconded and carried.)

Concerning the examination of school children, your Committee feels that whenever possible the physical examination of school children should be made by the family physician, but in those instances where a full-time school physician is employed to make such examination, we recommend that a closer cooperation be urged between the school physician and the family physician.

Your Committee also suggests that the family physician shows an equal enthusiasm in this examination as does the school physician.

I move the adoption of this recommendation.

(Motion seconded and carried.)

Regarding hospital interns, it is obvious to this House of Delegates that the leaders in medical education throughout this nation are making an efficient and effective effort through our medical schools to curtail the overproduction of physicians.

The entire purpose of this effort is being nullified by foreign physicians driven to America as a haven of refuge and by our own citizens, who are denied medical education here under the quota, and who rush to foreign shores for their degree. Eight hundred and forty-three (843) foreign physicians were licensed in New York State in the past five years.

Your Committee recommends in view of these well-known and well-established facts that the House of Delegates petition the Board of Regents of the New York Education Department to use every power within their means to correct this unwholesome and unjust state of affairs.

I move the adoption of this recommendation.

(Motion seconded and carried.)

With respect to the Physically Handicapped Children's Act, your committee recommends that no action is called for as the matter is still under consideration.

Concerning the licenses for psychologists, your committee approves the action of the Committee on Public Relations in not recommending this bill.

Relative to the report on patients in state institutions, your committee recommends that the state institutions maintain a closer relationship with the practicing physician.

In the light of the publicity that has been given to the menace of discharged patients, unfortunately paroled from mental and tubercular institutions, and in order to insure better care of those patients, and a greater protection

graph (1) of the Workmen's Compensation Law which states that 'Unless within thirty days after a bill has been rendered to the employer such employer demands an impartial examination of the fairness of the amount claimed the amount claimed shall be deemed to be the fair value of the services rendered' and

"WHEREAS, it is deemed both desirable and fair that the five per cent discount for early payment should be balanced by a reasonable penalty for delayed payment,

"Therefore, Be It Resolved, by the Medical Society of the County of Westchester that the House of Delegates of the Medical Society of the State of New York be urged to memorialize the State Industrial Commissioner to the effect of this resolution and to request, in the name of the State Medical Society that line 23 of the 'Minimum Medical Fee Schedule' be amended to provide that when a compensation claim is neither paid with discount nor controverted within thirty days, a cumulative penalty of one per cent per month shall be added to the face amount of the claim as rendered until full settlement has been made.'

Your Reference Committee on New Business C has given careful study to the resolution adopted by the Medical Society of Westchester and submitted to the House of Delegates by the representatives of the County of Westchester. This resolution recommends a penalty for delayed payment of compensation medical claims

Your Reference Committee recommends the subject matter noted in the annual report of the Committee on Workmen's Compensation reading as follows

"In the metropolitan area the Industrial Commissioner has permitted a deduction of five per cent from all bills of \$15.00 and over if paid within thirty days. There has been widespread dissatisfaction with this provision. It is much too large a discount and has not had the effect of stimulating prompt payment generally, but has actually had the effect of causing numerous disputes between physicians and carriers and employers. This rule should be rescinded. Surely without a penalty for failure to pay bills within the same period it is unfair and does not accomplish its purpose. It is recommended that the Commissioner be urged to rescind or modify this item of the fee schedule by adding a penalty of five per cent for non-payment within thirty days, and certainly not include it in any schedule which he may promulgate for the entire state."

In view of the approval of the House of Delegates of the annual report of the Committee on Workmen's Compensation your reference committee recommends the approval of the resolution of the Medical Society of the County of Westchester to memorialize the Industrial Commissioner to accept these amendments and recommendations of the Workmen's Compensation Committee.

I move the adoption of the committee's report.

(Motion seconded and carried.)

46 Report of Reference Committee on New Business C on Resolution re "Socialized medicine"

Section 26

DR. HAMILTON Your Reference Committee on New Business C having given careful study and consideration to the resolution introduced by Dr Samuel Fischhoff of the County of Kings on socialized medicine, recommends to the House of Delegates the disapproval of this resolution

Dr Fischhoff, in discussing the purpose of this resolution, stated that the resolution does not call for health insurance but calls for state medicine with medical control it calls for quality medical care, a divorce of the business of medicine from the practice of medicine, that it takes into consideration the fact that most of our people are unable to purchase quality medical care, and quoted from the Bulletin "On the Witness Stand"

THE SPEAKER A report has been adopted which does take care of most of the questions that are raised in this resolution, without committing the State Society to a program of state medicine.

The question is now before you. The report of the Reference Committee is that the resolution be not adopted. The adoption of the Reference Committee's report carries with it that implication, and that is its mandate.

(Motion seconded and carried)

47 Report of Reference Committee on New Business C on resolution re Section on Orthopedic Surgery

Section 16

DR. HAMILTON Your Reference Committee on New Business C, having given due study and consideration to the resolution introduced by Dr John J. Masterson of the County of Kings at the request of the orthopedic surgeons of the State, recommend to the House of Delegates that a scientific section on orthopedic surgery be established by The Medical Society of the State of New York.

I move its adoption

(Motion seconded and carried)

48 Report of Reference Committee on New Business C on resolution re Plans for Medical Care

Section 27

DR. HAMILTON Your Reference Committee on New Business C has given careful study and consideration to the resolution on "Plans for Medical Care" introduced by Dr Benjamin Davidson of the County of Kings and recommends that the House of Delegates disapprove the request for a special committee contained in this resolution as well as other recommendations contained therein.

(Motion seconded and carried)

42 Report of Reference Committee on
New Business A on resolution re Com-
pensation for Professional Services

Section 28

DR. CUNNIFFE In re the resolution on compensation for professional services introduced by Dr Benjamin Davidson of Kings County

"*Be It Therefore Resolved* by this House of Delegates that it hereby record itself in favor of compensation for all medical services rendered in all medical institutions of the State of New York, whether public or voluntary, and the officers of this Society make every effort to support the movement to make pay for professional work a legal and practical reality"

The committee recognizes that there has been a gradual extension of public payments for medical services both in the state and city in the past, and under proper safeguards, the further extension of such payments may be desirable and should be encouraged

The resolution as offered, however, is disapproved, as it is too drastic, and its provisions would lead in the direction of state medicine.

I move the adoption of the recommendation of the Reference Committee.

(Motion seconded and carried)

43 Report of Reference Committee on
New Business A in re Child Labor
Amendment

Section 20

DR. CUNNIFFE Re the resolution offered by the Bronx County Society, the resolution being

"*Resolved* that the New York State Medical Society go on record as favoring the adoption of the Child Labor Amendment to the Constitution of the United States

"*And Be It Further Resolved* that copies of this resolution be forwarded to the Governor, and the Chairman of the Senate, and Assembly Judiciary Committee."

This Child Labor Amendment has been before the different state legislatures for sixteen years without obtaining a sufficient number of endorsements to become a part of the Constitution. The New York State Medical Society has several times during the last few years opposed the provisions of the proposed amendment. It was also defeated in the last session of the New York State Legislature

Since a recent decision of the United States Supreme Court upheld the law restraining the transportation of goods produced under child labor from one state to another, the necessity for this amendment has been practically removed. We are informed also that a substitute amendment is under consideration and the committee feels that it is unwise to recommend any action until the provisions of the new amendment is known.

I move the adoption of the report of the reference committee.

(Motion seconded and carried)

44 Report of Reference Committee A on
Medical Assistance in the promotion and
administration of the Motor Vehicle
Laws

Section 34

DR. CUNNIFFE Re Resolution of the Genesee County Medical Society "WHEREAS, there is annually reported an increase in automobile fatalities by the Department of Motor Vehicles, and

'WHEREAS, the physicians of the State are actively interested in preventing deaths from disease and injury,

"*Be It Therefore Resolved*, that we take such steps as may be necessary or desirable to assist the proper state authorities, with medical assistance, in the promotion and administration of the Motor Vehicle Laws"

The Committee heartily endorses the purposes of this resolution and recommends that the Legislative Committee assist the proper state authorities, with medical assistance, in the promotion and administration of the Motor Vehicle Laws, and that the members of the New York State Medical Society do all in their power to promote the administration of these laws, and to decrease the fatalities caused by motor accidents

I move the adoption of the report of the reference committee.

(Motion seconded and carried)

45 Report of Reference Committee on
New Business C on resolution recom-
mending a penalty for delayed payment of
compensation medical claims

Section 22

DR. HAMILTON Re the resolution adopted by the Medical Society of the County of Westchester, May 18, 1937, for submission to the House of Delegates of the Medical Society of the State of New York

"WHEREAS, the Minimum Medical Fee Schedule for Medical Treatment and Care of Injured Employees, as established by the State Industrial Commissioner under the Compensation law, applying to the 'Metropolitan Area', provides under line 23 that a discount of 5% may be deducted from all medical bills in amounts of \$15 00 or more if paid within 30 days of receipt by the insurance carrier, and

"WHEREAS, the expressed purpose of this provision is "to facilitate prompt payment of medical bills" and

"WHEREAS, certain insurance carriers permit many of their uncontroverted claims to remain unpaid many months after the discount period despite the provision of Section 13-g, para-

refuse employers and self insurers preferential rates below the minimum fee schedule for medical services under the Workmen's Compensation Act.

I move its adoption

(Motion seconded and carried.)

The second recommendation is that Society go on record as approving the Esquirol Bill, Senate Int. 1962, introduced April 15, 1937 (An Act to amend the Workmen's Compensation Law with respect to compensation)

I move its adoption.

DR. BEDELL May we know what is in the bill, or the import of the bill?

DR. O'GORMAN The bill is in regard to medical services, in detail, to correct errors that have existed in the bill already in. The Workmen's Compensation Committee has presented the bill to the Executive Committee and it was introduced last year. We feel that the Workmen's Compensation Committee's effort in this matter should be restated and reaffirmed by the act of the delegates

THE SPEAKER The Esquirol bill was introduced at the request of our Legislative Committee after its provisions were approved by the Executive Committee, on a mandate from this House of Delegates in its previous session. This bill corrects abuses that still exist in the Workmen's Compensation Law. The bill was not passed. It died in committee. The reference committee having this matter in hand recommends to this House that the bill be reintroduced with the approval of this House of Delegates. That is the way I understand it.

DR. O'GORMAN I move the adoption of this recommendation

(Motion seconded and carried)

52 Report of Reference Committee B on Resolution on State Medicine

Section 18

DR. MCGOLDRICK In re resolution submitted by Bronx County

"WHEREAS, the NEW YORK STATE JOURNAL OF MEDICINE in a leading editorial of May 15, 1937, acknowledges the existence of State Medicine in a limited form, and

"WHEREAS the same editorial ventures the prediction that the trend for state medicine, if left unguided, will, by a series of progressive encroachments, completely displace private practice, and

"WHEREAS, it is the opinion of organized medicine, as expressed in the above named editorial, that the medical profession should assume leadership in that movement with a view to obviating any injustice that might be suffered by the profession, or by the public through precipitate action,

"Therefore, Be It Resolved, that the speaker of the House of Delegates be authorized and instructed to appoint a committee at this session for the immediate study of this question, and

"Be It Further Resolved that this committee shall report from time to time its findings in the STATE JOURNAL, and

"Be It Further Resolved, that no definite recommendation of this committee shall be acted upon by the State Society without first submitting the question to a referendum of the entire membership of the State Society"

Your Committee reports because such a committee for this and other purposes is recommended elsewhere to this body of delegates (and approved by it),

And because the new committee's findings will be reported to the Society as soon as it is practice to do so, and because no action binding the State Society may be taken without proper authorization, we recommend that these submitted resolutions be disapproved

I so move.

(Motion seconded and carried.)

53 Report of Reference Committee B on Resolution re Preventive Medicine

Section 25

DR. MCGOLDRICK This reference committee agrees with the statement that many lives are lost and many persons suffer needless illness because the public does not sufficiently understand that the medical profession is ready and qualified to aid them in health, as well as in disease

This committee recommends that each physician and every organization be called upon to continue and increase their efforts to inform the public of the need and value of personal preventive medicine and the benefits that may be derived therefrom

This committee further recommends that the basic health examinations serve the best purposes of the individual examined and the public when made in the office of and by the family physician.

I move the approval of this report.

(Motion seconded and carried)

54 Report of Reference Committee on New Business B on Resolutions on subject "Medical Indemnity Insurance Organizations"

Section 9

DR. MCGOLDRICK Resolution of the Medical Society of the County of Albany on the subject Medical Indemnity Insurance Organizations

"WHEREAS, the Medical Society of the State of New York has always opposed the enactment of any compulsory health insurance law, and

"WHEREAS, it is a recognized fact that most states or countries having compulsory health insurance began by promoting voluntary insurance or indemnity schemes, and

"WHEREAS, there has been a bill before the Legislature providing legislation that would

49 Report of the Reference Committee on the report of the Committee on Trends

Section 12

DR. LOUIS H. BAUER One cannot read the report of the Committee on Trends without realizing the enormous amount of work accomplished by this Committee, enormous for any committee and particularly so when it is considered that each member of the committee was chairman of still another committee or engaged in some equally time-filling work for the Society.

In these days of improved and new methods of treatment, and constant social upheaval, not only the physician but also the layman needs to be kept informed on subjects that are of vital interest to them. The work of this committee then is paramount in its effect on the education of the public and physician in economics and the newer therapeutics.

The thanks of the Society is due this committee for its work.

The committee seems to have succeeded in reaching a complete cross-section of those most apt to disseminate still further the information sent out. It is vital that this work be continued and, if possible, increased. It is difficult, however, to see how the committee can increase its activities except through the recently organized Speakers' Service of the Public Relations Bureau and that only through the cooperation of the County Societies. The Committee has requested that there be such cooperation and the Reference Committee has therefore drawn up the following resolution which it feels the House of Delegates should adopt.

"WHEREAS, the Committee on Trends has done valuable work in educating both the profession and the laity in professional and economic changes, and,

"WHEREAS, the value of the recently organized Speakers' Service project will be greatly enhanced by the cooperation of the County Societies,

"Therefore, Be It Resolved, by the House of Delegates of the Medical Society of the State of New York, assembled in annual meeting at Rochester, New York, on May 24th, 1937, that each County Society is urged to appoint a special committee of not more than three members, to cooperate locally with the Committee on Trends of the Society in the furtherance of the Speakers' Service project."

I move the adoption of the Committee's report, together with the resolutions I have just read.

(Motion seconded and carried.)

DR. ROONEY The Commissioner of Health of the State of New York is with us. I move that he be granted the privilege of the floor and be escorted to the rostrum.

THE SPEAKER Will Dr. Mitchell escort the Commissioner of Health to the rostrum?

50 Report of Reference Committee on report of Legal Counsel

DR. VEEDER Reading the report of the legal counsel of the Society, your committee is impressed with the increasing volume of work performed by this department. Although the number of litigation instituted during the year was about the same as the previous year, a substantial increase was made in disposing of pending cases. The articles published in the JOURNAL, prepared by the legal department pertaining to court decisions of a medical nature, have been timely and informative. County societies and individual physicians have requested opinions on legal matters in ever increasing numbers. In each instance the office of the legal department has been most gracious in complying with these requests and has rendered opinions that have been valuable to both the individuals and the county societies requesting them, and to the State Society as a whole. The report indicates that the Counsel, Mr. Brosnan, and the attorney, Mr. Clearwater, have conducted this department in a highly efficient manner and deserve the commendation of the Society.

I move its adoption.

(Motion seconded and carried.)

51 Report of Reference Committee on report of Committee on Workmen's Compensation

DR. O'GORMAN Your Reference Committee recognizes the vast amount of work accomplished by our Workmen's Compensation Committee through arduous detailed effort and calls your attention to the Committee's contacts and conferences with every agency, private and public, interested in the care of injured workmen. The resulting state-wide advance in understanding and appreciation of our Society's objective to safeguard the interests of the injured workmen with approved medical care at a just cost has our enthusiastic approval. We wish to remind you there are well-organized influences making an endeavor to break down many provisions of the present law. The physicians of the State must maintain constant contact and pressure to offset such influence on the Commissioner and the Department of Labor.

In harmony with the Workmen's Compensation Committee's activities, we recommend

1 That the industrial Commissioner be requested to refuse employers and self insurers preferential rates below the minimum fee schedule for medical services under the Workmen's Compensation Act.

2 That the Society go on record as approving the Esqurol Bill, Senate Int. 1962, introduced April 15, 1937. (An Act to Amend the Workmen's Compensation Law with respect to Compensation.)

We recommend re-introduction of this bill. There are two recommendations. I move the adoption of the first recommendation, that the Industrial Commissioner be requested to

STATE JOURNAL, and endorse his opinion in regard to the retention of the district branches.

We endorse his comment in regard to the employment of a full-time secretary, but due to the fact that this will be discussed before the House of Delegates in connection with the Report of the Committee on Revision of Constitution and By-Laws, would advise no action at this time.

We approve his second comment in regard to Miss Baldwin. This will be brought before the House of Delegates later at this session by a recommendation of the Executive Committee, so we suggest action be taken on this matter at that time.

Your Committee considers this an excellent detailed report of a very efficient secretary.

We move the adoption of this report.

(Motion seconded and carried.)

59 Supplementary report of the Board of Censors

Section 61

THE SECRETARY. In the matter of discipline imposed by the Medical Society of the County of Queens on its two members Drs F Raymond Surber and Thomas F Draper, the Board of Censors of the Medical Society of the State of New York, on April 24, 1937, heard a second appeal.

There were present at this meeting Drs Floyd S Winslow, Peter Irving, Terry M Townsend, Carl Boettiger, Murray M Gardner, Leo P Larkin, Thomas W Maloney, H Wolcott Ingham, Mr Lorenz J Brosnan, Counsel, and Mr Thomas H. Clearwater, attorney.

There were also present Dr James F Reuling, Jr, president, and Dr Herbert L. Langer, chairman of the Board of Censors of the Medical Society of the County of Queens.

The appellants were represented by counsel, Mr Lloyd Paul Stryker.

After full consideration of the record of further action by the Medical Society of the County of Queens, to which the matter had been remanded for consideration in the light of additional evidence, and which Society reaffirmed its original decision, the Board of Censors of the Medical Society of the State of New York unanimously adopted the following resolution:

That it be the decision of the Board of Censors on this appeal that the evidence does not sustain the charges which have been made against these appellants, and that, therefore, the decision of the Board of Censors of the Queens County Society, finding these men guilty of such charges, must be reversed, the charges dismissed and the appellants reinstated to membership in good standing in their county society as of the date of their original suspension."

THE SPEAKER. Referred to Reference Committee on Report of Board of Censors.

60 Report of Reference Committee on Report of the Council

DR. CARPENTER. The first major event reported by and acted upon by the Council was in regard to the mandate of the 1936 House of Delegates, providing for the introduction to the State Legislature of a law limiting the administration of anesthesia to physicians and dentists. This action was rescinded at the meeting of the Council held December 10, 1936. The present House of Delegates was informed concerning this action, as a referendum was submitted to them as provided by the by-laws. The action of the Council was approved by a vote of 157 to 8.

Unquestionably in view of the evidence presented and conditions existing, this action is wise. We believe, however, that this legislation should still be one of our objectives, thereby maintaining administration of anesthesia as a special branch of medicine. To this end we would suggest that courses be established to train physicians in this specialty. We move this be approved and the matter referred to the Legislative Committee to use their efforts to secure the passage of suitable legislation at as early a date as practicable.

On recommendation of the Committee of Public Health and Medical Education, the council passed a resolution request the State Department of Education to prepare a pamphlet for issue to all licentates, especially recent graduates, pamphlet to give information in regard to the technicalities of the Educational Law, which are to be observed by all physicians and especially in regard to the matter of local registration and annual registration.

The committee approves of this resolution and moves its adoption.

(Motion seconded and carried.)

We have made a very careful study of the appointees of the Executive Committee on the various standing committees approve the same and consider these appointments of a very high order.

We observe at the first meeting of the Executive Committee on April 28, 1936 at the suggestion of the President, invitation was extended to the five trustees the executive officer first vice-president, director of Workmen's Compensation, chairman of the Committee on Trends and the Director of Public Relations to attend the meetings of this committee and were accorded the privilege of the floor.

In the opinion of our Committee, this was a very sensible innovation as it made available to the Executive Committee much valuable information and advice which would assist them in making important decisions. The reference committee recommends continuance of this procedure.

We move its adoption.

(Motion seconded and carried.)

The following resolution was passed by the Executive Committee:

"The Medical Society of the State of New York urge that the reorganization of the Fed-

enable the creation of medical indemnity insurance organizations,

"Be It Therefore Resolved, that the Medical Society of the State of New York maintain its position of opposition to all schemes of this character unless a decision to the contrary is reached in the House of Delegates' meeting either in regular or special session."

This committee recommends the adoption of these resolutions

I so move.

(Motion seconded and carried)

55 Report of Reference Committee on New Business B on Resolution re Physicians' dismissal from hospitals without hearing

Section 21

DR. MCGOLDRICK "WHEREAS, physicians serve on hospital staffs of municipal and voluntary institutions for long years without compensation, and

"WHEREAS, these physicians oftentimes after many years of faithful and diligent service are summarily dismissed without being granted a hearing by the Board of Directors of these institutions,

"Be It Resolved, that the House of Delegates of the Medical Society of the State of New York go on record as opposed to any such dismissal on the part of the directors and boards of these institutions without a hearing"

This committee believes that this is a matter for local county societies and not for the State Society

I move the adoption of this report

(Motion seconded and carried)

56 Report of Reference Committee on the Report of the President

DR. WOODEN The reference committee on the Report of the President had a light task. Fortunately for the time and the nervous system of this deliberate assembly, the report is devoted largely to an outline of the activities of a year of harmony. This tranquility is reflected in the report of your reference committee. It is obvious that the office has functioned energetically and that a major contribution has been made in the form of increased cooperation with groups with whom we share common problems. A notable example is the wholesome relationship that has been established with the State Hospital Association. The single recommendation that special attention be devoted to five specific problems—hospital insurance, tuberculosis, crippled children, welfare and nursing problems—by assignment to either regular or special committees, seems to this committee to represent a wise prophetic grasp of subjects for near-future study. Specific suggestions as to the assignment of these problems may well await the solution of the study of revision and reconstruction of by-laws

The Committee recommends the adoption of the report of the President as a whole.

(Motion seconded and carried)

57 Report of Reference Committee on the Address of the President-Elect

Section 5

DR. WOODEN The Reference Committee commends the address of the President-Elect as worthy of careful reading on the part of the members of the House by reason of its fine expression of the needs and aims of organized medicine. Specifically, the committee approves of these recommendations

That county and district branch meetings give considerable attention in their programs to the subjects of materia medica, therapeutics and pharmacology and that the JOURNAL Management Committee be requested to establish a department in such a manner, in their wisdom as will increase the practical knowledge and skill in these subjects

That during the coming year, in county and district branch meetings the subject of preventive medicine be presented actively and its practice by the profession encouraged in every possible way

That contributions on preventive medicine to the STATE JOURNAL be offered by the membership and sought by the JOURNAL Management Committee

That whenever and wherever possible lay audiences throughout the state be provided with addresses on preventive medicine, such provision to be made by county societies, district branch officers, the Public Relations Bureau or by concerted action.

The committee recommends the adoption of the address of the President-Elect, and its contained resolution, as a whole.

(Motion seconded and carried)

58 Report of Reference Committee on Report of the Secretary

DR. CARPENTER We note the increase in 1936 of the Membership in the State Society by approximately eleven hundred members and appreciate that this, coupled with the changes in the Compensation Laws and the increased activity of the Committee on Trends and Public Relations, entails a large amount of administrative work, increasing the duties of the Secretary

We approve heartily of the closer relationship between the Society and the New York State Department of Health, especially with regard to pneumonia and syphilis control and maternity and child welfare.

We believe the invitation of Committee chairmen and trustees to the Executive Committee meetings and sending of agenda to those attending tends to increase efficiency. We commend the secretary for attending such a large number of Society meetings, his work on the

Your Committee has studied the excellent report of the JOURNAL Management Committee. We feel every member of the State Society has reason to be proud of the growth of the JOURNAL under the present management. The increase in size is gratifying, but more important is the improvement in the scientific articles published. There is also a marked change for the better in the quality of the advertising matter. All this has been accomplished at a minimum added expense. The improvement in the Directory is noted and commended.

Your Committee feel that the work of this Committee deserves the highest commendation. We move its adoption.

(Motion seconded and carried.)

At a meeting of the Executive Committee held June 11, 1936, Dr Nathan B Van Etten, Trustee, asked and was granted the privilege of the floor. He paid a very fine, well-deserved tribute to Miss Baldwin, who has worked in the interest of the Medical Society of the State of New York for many years. She has been of great assistance to presidents, secretaries, and treasurers as well as other members of the Society. She has been an encyclopedia of knowledge in regard to all matters pertaining to the Society. He suggested she be retired with the title of Office Manager Emeritus. Motion was made by Dr Kopetzky, seconded by Dr Goodrich, and unanimously carried that Miss Baldwin be retired with the title of Office Manager Emeritus at such time as was decided by a committee of the President, Treasurer, and Secretary. That it be recommended to the Board of Trustees that from the date of her retirement she receive as long as she lives a salary at the rate of \$3,000.00 per annum. The Executive Committee recommends that the House make permanent this action.

I move that this be made permanent at this time, and move the adoption of this report.

DR. BEDELL I would like to move that in addition to this, we send Miss Baldwin a certificate suitably engraved, expressing to her in that way, as well as in a financial way, our great appreciation of her record.

No man could ever have been president of this Society without appreciating the immense value of her services to every one of us, I mean members as well as officers.

I make this motion as an amendment and trust that the Reference Committee will accept it and make it a chief part of their report.

DR. ROONEY I second the motion
(Applause)

THE SPEAKER The Reference Committee's report has this suggested amendment. I presume it will be accepted. I, personally, am so appreciative of all that has been said that I want to put this to a rising vote. I want Miss Baldwin to come up on the platform here and receive the vote.

(A rising vote being taken, the motion was unanimously carried.)

DR. CARPENTER We believe that the conferences arranged between a committee from the Medical Society of the State of New York with a committee from the State Hospital Association will result in a better understanding and closer cooperation between these two organizations.

Your Reference Committee is much impressed by the results of the conferences between the committees of the State Medical Society and the State Hospital Association. Definite articles of agreement have been set up by these committees as is noted in their report which we have given very careful study. Other points are still under discussion which will probably be agreed upon at later conferences.

This movement certainly is a step forward, as it will clarify misunderstandings between the hospital management and the medical profession. In our opinion this committee deserves the highest commendation for the tactful way in which it has negotiated a very difficult situation.

We recommend that this committee be continued. We move its adoption.

(Motion seconded and carried.)

DR. CARPENTER Your Reference Committee has read the voluminous report of the Committee on Economics on the subject of medical expense indemnity insurance. We appreciate the tremendous amount of intelligent work that has been reported. Also we have studied the report of the Legislative Committee on this subject. There may be a place for some type of insurance of this character. However, it is a question if it is advisable for the Medical Society of the State of New York to definitely endorse any plan of this kind at this time.

We believe further consideration of this subject is necessary for the reason that in many instances beginning with the endorsement of a voluntary insurance, the next step in the process if these companies should tend to become insolvent, would be compulsory health insurance.

Therefore we recommend its disapproval.
(Motion seconded.)

DR. ELLIOTT You gentlemen in this House need no detailed picture of the economic problem which faces a very large part of our population at any time when more than minor medical care is needed. That large group is now compelled under the force of necessity to surrender their status of self-reliance and independence and accept the tender of free medical care. They should have a mechanism through which by means which they are able to provide they can retain that independent self-support in the matter of medical care and instead of being forced to accept a tender of free medical care they should be made able to compensate each doctor for such service as they need.

Under the wording of our law it is not pos-

eral Government combine in one department all medical and health activities, making this a separate and distinct department, and urge especially the nomination as chief executive officer of such a department of a qualified physician with a record of achievement in administration"

This committee approves of this resolution and moves its adoption by the House of Delegates

(Motion seconded and carried)

The Executive Committee recommends that physicians engaged in "group practice" should remain within the same framework of restrictions as to their conduct, as though the activity were that of an individual physician. In other words, we feel that a group may not obtain publicity by any means in lay publications, that it should not solicit or advertise, that it should not claim superior quality or service, should not practice competitive fees against the individual physician of the community. If the group conforms to this, and relies solely upon the recognition of its service by the people of the community as its sole means of acquisition of patronage, it would seem to be a proper and fair activity

We approve of this recommendation and move its adoption

(Motion seconded and carried)

Upon recommendation of the Committee on Workmen's Compensation procedures, the Executive Committee went on record as favoring the promulgation of a state-wide fee schedule, the same as already set for the metropolitan area

We approve this recommendation and move its adoption

DR. BEDELL Speaking for at least a few of the up-state districts, I urge that this recommendation be disapproved until we, of the up-state districts, have had further time to observe the workings of the bill adopted in the lower section. I believe that time will show that some of the disadvantages which have been reported from the lower part of the state will be corrected, and we, up state, will not be subjected to the experience of living them down.

(Delegates from Broome and Greene Counties concurred that the recommendation should be disapproved)

(Dr. Podvin of the Bronx, spoke on behalf of the Industrial Council in favor of the adoption of the recommendation)

(A vote was taken on the motion and the motion to adopt the report of the Reference Committee was carried)

DR. CARPENTER We note there will be a session on general and regional anesthesia this year, in accordance with the suggestion presented to the last House of Delegates. At the suggestion of Dr. James Ewing of New York, the Executive Committee recommends the creation of a session or section on pathology (See section 31)

Your Committee moves that a Section on Pathology and Clinical Pathology be created (Motion seconded and carried.)

In conformance with the by-laws, the Executive Committee received the nomination for honorary membership, Dr. Jose Arce.

"Gentlemen the undersigned members desire to nominate for honorary membership in the Medical Society of the State of New York Dr. Jose Arce, Professor of Surgery, University of Buenos Aires, Buenos Aires, Argentine."

"We beg to present this at the meeting of the House of Delegates in May 1937, as prescribed by the By-laws, Chapter I, Section IV

"Very truly yours,

FLOYD S. WINSLOW
JOSEPH J. ELLER
CHAS. GORDON HEYD "

The Executive Committee recommends the By-laws requiring the wait of one year be suspended and that the House of Delegates proceed to elect Dr. Jose Arce to honorary membership at the 1937 meeting

I move suspension of the By-laws and election of Dr. Jose Arce at this time

THE SPEAKER This recommendation is declared out of order. The nomination lays over for one year and takes the usual course

DR. CARPENTER Recommendation was made by the Economics Committee which would rescind sections A, B, C, D and E of Proposition III of the Booth Report, restating the same under heading A to E as noted in the report of the Executive Committee. This would define and clarify the meaning of hospital care in contradistinction to medical care as covered in the group hospital insurance plan. This would seem desirable and we move its adoption.

We wish to express our approval of the resolution of the Board of Regents which follows

"That on applications filed after October 15 1936 no license of a legally constituted Board of Examiners in any foreign country shall be endorsed pursuant to the provisions of Section LI of the Educational Law until the applicant shall pass the licensing examination prescribed by law and regent's rule."

The following resolution was passed by the Executive Committee

"That a temporary binder be issued to any applicant for membership in the Medical Society of the State of New York as soon as the Secretary of the County Society advises the secretary of the State Society that his application for membership, together with his check for dues has been received and placed on file with the County Society, provided that when the applicant is finally elected, the binder is to be closed by the issuance of a certificate of insurance dated as of the date of issue of the binder, provided that if the applicant fails of election the binder will be cancelled as of the date of the issuance of the application and the applicant would enjoy no protection thereunder

This resolution seems wise and we move the adoption of the same.

(Motion seconded and carried.)

Your Committee has studied the excellent report of the JOURNAL Management Committee. We feel every member of the State Society has reason to be proud of the growth of the JOURNAL under the present management. The increase in size is gratifying, but more important is the improvement in the scientific articles published. There is also a marked change for the better in the quality of the advertising matter. All this has been accomplished at a minimum added expense. The improvement in the Directory is noted and commended.

Your Committee feel that the work of this Committee deserves the highest commendation.

We move its adoption

(Motion seconded and carried.)

At a meeting of the Executive Committee held June 11, 1936, Dr Nathan B Van Etten, Trustee, asked and was granted the privilege of the floor. He paid a very fine, well-deserved tribute to Miss Baldwin, who has worked in the interest of the Medical Society of the State of New York for many years. She has been of great assistance to presidents, secretaries, and treasurers as well as other members of the Society. She has been an encyclopedia of knowledge in regard to all matters pertaining to the Society. He suggested she be retired with the title of Office Manager Emeritus. Motion was made by Dr Kopetzky, seconded by Dr Goodrich, and unanimously carried that Miss Baldwin be retired with the title of Office Manager Emeritus at such time as was decided by a committee of the President, Treasurer, and Secretary. That it be recommended to the Board of Trustees that from the date of her retirement, she receive as long as she lives a salary at the rate of \$3,000.00 per annum. The Executive Committee recommends that the House make permanent this action.

I move that this be made permanent at this time, and move the adoption of this report.

DR. BEDELL I would like to move that in addition to this, we send Miss Baldwin a certificate suitably engraved, expressing to her in that way, as well as in a financial way, our great appreciation of her record.

No man could ever have been president of this Society without appreciating the immense value of her services to every one of us, I mean members as well as officers.

I make this motion as an amendment and trust that the Reference Committee will accept it and make it a chief part of their report.

DR. ROONEY I second the motion.

(Applause)

THE SPEAKER The Reference Committee's report on this suggested amendment. I presume it will be accepted. I, personally, am so appreciative of all that has been said that I want to put this to a rising vote. I want Miss Baldwin to come up on the platform here and receive the vote.

(A rising vote being taken, the motion was unanimously carried.)

DR. CARPENTER We believe that the conferences arranged between a committee from the Medical Society of the State of New York with a committee from the State Hospital Association will result in a better understanding and closer cooperation between these two organizations.

Your Reference Committee is much impressed by the results of the conferences between the committees of the State Medical Society and the State Hospital Association. Definite articles of agreement have been set up by these committees as is noted in their report which we have given very careful study. Other points are still under discussion which will probably be agreed upon at later conferences.

This movement certainly is a step forward, as it will clarify misunderstandings between the hospital management and the medical profession. In our opinion this committee deserves the highest commendation for the tactful way in which it has negotiated a very difficult situation.

We recommend that this committee be continued. We move its adoption.

(Motion seconded and carried.)

DR. CARPENTER Your Reference Committee has read the voluminous report of the Committee on Economics on the subject of medical expense indemnity insurance. We appreciate the tremendous amount of intelligent work that has been reported. Also we have studied the report of the Legislative Committee on this subject. There may be a place for some type of insurance of this character. However, it is a question if it is advisable for the Medical Society of the State of New York to definitely endorse any plan of this kind at this time.

We believe further consideration of this subject is necessary for the reason that in many instances beginning with the endorsement of a voluntary insurance, the next step in the process if these companies should tend to become insolvent, would be compulsory health insurance.

Therefore we recommend its disapproval.

(Motion seconded.)

DR. ELLIOTT You gentlemen in this House need no detailed picture of the economic problem which faces a very large part of our population at any time when more than minor medical care is needed. That large group is now compelled under the force of necessity to surrender their status of self-reliance and independence and accept the tender of free medical care. They should have a mechanism through which by means which they are able to provide, they can retain that independent self-support in the matter of medical care and instead of being forced to accept a tender of free medical care they should be made able to compensate each doctor for such service as they need.

Under the wording of our law it is not pos-

sible to set up a system in which the people, for a small sum, can engage an indemnity cash reserve to meet such emergencies

I do not think that the interest of the doctors of this state is being served by holding up before us a phantom fear that all voluntary insurance leads to compulsory insurance. The thing that has led to compulsory insurance in foreign countries has been that they were not practicing insurance in the true sense of that term, but were disguising a contract practice of medicine, and out of such a system there inevitably arises wrongs which require governmental supervision. It has been in consequence of that abroad that they have had inevitably a state control and compulsory health insurance system.

The surest defense that this Society can set up against state medicine, against a compulsory health insurance for the people of low income, is to establish a mechanism through which these people may have and enjoy an independence and through which we may continue to practice in private rather than to be subjected to some system of state control or some system of contract practice.

It seems to your Committee on Economics that is much wiser since our insurance department, a public agency, has turned to the organized medical society and said, "Here is a problem, it must be solved, we believe that you folks are more intimately acquainted with the real problem of providing medical care and we believe that you, in cooperation with us, can solve this thing in an American way, that we can defend the American people against a foreign, alien method of insurance by developing, through cooperation of this agency and your organized body, a system which will preserve American medicine for American people."

It has been said that we have no experience and that the problem of setting up rates is unsurmountable. Until we start, how are we going to have experience? If we indicate a lack of concern in our own intelligence, our ability to tackle the application of a sound principle for the good of the people whom we serve and for the protection of the professional heritage which has been handed down to us, we are not living up to our obligations.

DR. READ, *Kings* As a member of this committee we might agree with the wishful thinking of our Economics Committee chairman. We do not deny that there may be a means which can be worked out. The conflicting theories of the various medical societies on the wisdom of the details of this proposal offered to us was such that this committee felt, as it stated in its recommendation, that another year's consideration was necessary before this body could take any definite action. Therefore, we recommended that it be held over for consideration and we disapproved more formal action at this time.

(On motion, seconded and carried, Dr Wetherell, a member of the Committee on Economics, although not a member of the House

of Delegates, was accorded the privilege of the floor)

DR. WETHERELL There has been a great deal of confusion about this matter of sickness indemnity insurance. It is not "wishful thinking", with due respect to the previous speaker, on the part of the chairman of the Medical Economics Committee, which consists of not only the chairman, but at least a dozen. We have been working on this thing for a matter of six years, so that it is not something that has just arisen.

The study has been completed. A law has been drawn which gives control to the Medical Societies of the various counties.

It is simply this: you pay so much a year to indemnify you against three hundred dollars' worth of doctors' bills in a year. I have gone over it very carefully and it is exactly the same in its procedure as hospital insurance which we have now, which indemnifies you against three weeks in the hospital.

There have been various red herrings drawn across this trail and one is the Brattleboro plan, which has nothing to do with it.

The important thing to remember is that we are trying to do something for this group of earners in the middle class, such as we are, the white collar class, so that they may, through a non-profit mutual sickness insurance indemnity group indemnify themselves against doctors' bills.

The arguments against it are that it is an inroad to state medicine. It is no more an inroad to state medicine than the present insurance is because if more money is needed the group will simply put on a larger premium the next year.

The medical profession has control over the qualifications of the doctors, according to the law which was drawn up and presented to the Executive Committee and which we thought was going through, but which didn't go through, for reasons which I do not know.

The whole thing is a fight against socialized and state medicine.

DR. FISCHOFF I do not know how many of you have gone over the report on indemnity insurance, but I went over it rather carefully and it has several weaknesses which I think the members of this House ought to know about.

In the first place, in addition to those objections which have been expressed already, it has these weaknesses from the standpoint of the man applying for this insurance, it is going to be costly because the elements of minor illnesses and the first stages of major illnesses are often confusing. In other words there will be a deductible clause for one or two weeks, the same as we have a deductible clause in our automobile collision insurance. If the insured has to pay not only the cost of this premium for the first week or ten days or for the minor illnesses, he still would have to pay the doctor for that sort of thing, so that it would be an additional cost to him.

Secondly, so far as the contract is concerned, there is a certain amount of limitation on the choice of doctors and hospitals whenever he needs the hospital.

Thirdly, there would be a limitation so far as the type of disease is concerned, and the course of treatment.

There is going to be a constant bickering and disagreement as to what is known as the initial part of illness.

So far as I am concerned I do not know what the initial part of acute appendicitis is.

Then the question of negligence on the part of the patient will have to be considered. Since he cannot collect for a doctor's bill within a certain period of time, he will not call a doctor if he has to pay for it himself.

Then a body will have to be created to investigate the eligibility of applicants for this type of insurance. That is what the bill calls for, and here is the problem: the bill does not state exactly who is eligible. It says, "The low-income group." Whatever that means I do not know.

Then of course comes the question of the number of children in the family and the social conditions he lives under. And we have not defined "indigent" yet.

Then, too, you have the problem of padding bills. There are those who, having paid their premiums, are going to try to get as much back as they can.

Further, in order to arrange for this thing you will have to have some sort of fixed fee because you will have to eliminate the sliding scale fees. If you are going to give the doctor a smaller fee for doing this type of work, in order to make up for that, he is going to make more calls. Incidentally this would have a great tendency to lower doctor's fees. If under this plan a man is charged \$3.00 and in private practice he has to pay \$5.00, it is going to create a situation where the first thing you know all such charges will be three dollars.

DR. ELLIOTT After an illustration of how completely a thing can be misunderstood and misrepresented, and how utterly inadequate such a discussion as this can be, in the consideration of one of the most important questions that has ever come before this House, I sympathize with the Executive Committee which hesitated to assume the responsibility of putting this Society on record for this. I am reminded of the definitions of "conservative" and "radical." A conservative believes nothing should ever be done the first time. The radical believes nothing should be done twice. This thing is in between.

I move a substitute motion on an amendment to the resolution of the Reference Committee that this House instruct its ad interim legislative body, whatever it may be, the Executive Committee or the new Council, to act for this House when the economic group have satisfied that ad interim body that this is a fair and proper procedure for the State Society. I propose that amendment on the ground that the

smaller body, with greater time, can go into the details, which would take us two or three hours here.

(Substitute motion seconded and carried.)

THE SPEAKER The report of the Reference Committee in regard to the report of the Committee on Economics on the subject of Medical Expense Indemnity Insurance is lost.

DR. CARPENTER I move the adoption of the report of the Reference Committee on the report of the Council as amended.

(Motion seconded and carried.)

61 Report of the Reference Committee on the Report of the Board of Censors

Section 59

DR. CARPENTER The report of the Board of Censors shows that two sessions were held during the year. The first on December 10, 1936, to hear the appeal of Drs. Thomas F. Draper and F. Raymond Surber from the action of the Medical Society of the County of Queens suspending them from the rights and privileges of membership for a period of six months from October 27, 1936. This matter was referred back to the Board of Censors of the Medical Society of the County of Queens for reconsideration, with medical evidence which had been submitted to the Board. The second meeting was held April 24, 1937, to hear a second appeal by Drs. Surber and Draper. After a full consideration of the record of the Medical Society of the County of Queens and combined with the additional evidence, the Board of Censors of the Medical Society of the State of New York found that the evidence would not sustain the charges against these appellants, reversed the action of the Board of Censors of the Queens County Society and ordered the reinstatement of these members at the date of their original suspension.

We move the approval of the Board of Censors' action.

(Motion seconded and carried.)

62 Report of the Reference Committee on the report of the Councillors

DR. CARPENTER We have carefully studied the report of the Councillors, which consisted principally of a review of the programs and actions taken at the eight district branch meetings. In commenting upon these meetings, it would seem that they were of exceptional scientific value and the attendance very satisfactory.

We move the adoption of this report.

(Motion seconded and carried.)

63 Resolution re Kline-Todd Radiology Bill

Section 73

THE SPEAKER This is a resolution from the Medical Society of the County of Westchester.

WHEREAS, radiologists through their organization, sponsored a bill in the 1937 New

York State Legislature known as the Kline-Todd Radiology bill, and

"WHEREAS, such bill defined radiology and proposed needed safeguards against the commercial exploitation of radiology, and

"WHEREAS, this bill was killed by the chairman of the Senate Committee who refused to report it out of committee,

"*Therefore, Be It Resolved*, that the Medical Society of the State of New York approve the principles of the Kline-Todd Radiology bill and direct the proper committee to reintroduce and support a similar measure at the 1938 New York State Legislature."

THE SPEAKER This will be referred to Reference Committee on New Business A

64 Re Delegates to Connecticut and New Jersey Society Annual Meetings

Section 70

THE SECRETARY "WHEREAS, very cordial relations with the State Medical Societies of Connecticut and New Jersey have recently been established in connection with improving the Directory, and

"WHEREAS, the Connecticut State Medical Society asked that the Medical Society of the State of New York appoint two delegates to its annual meeting,

Be It Resolved, that the Medical Society of the State of New York ask the State Societies of Connecticut and New Jersey to designate to its annual meetings two delegates hereafter, and

Be It Further Resolved, that two delegates be appointed to the Connecticut State Medical Society"

THE SPEAKER Referred to Reference Committee on New Business B

65 Communication from Women's Medical Society of New York State

Section 72

THE SPEAKER We have the following from The Women's Medical Society of New York State

The Women's Medical Society of New York State at their 31st Annual Session in Rochester, May 24, 1937, unanimously endorsed the following communication from the Women's Medical Association of New York City

"Inasmuch as one state has tried the experiment of requiring a blood Wassermann test before granting a license for marriage, and has found that it has worked out satisfactorily and without undue hardship, and inasmuch as gonorrhea as well as syphilis should be guarded against, and inasmuch as gonorrhea in women is more difficult of diagnosis than in men—and inasmuch as the Complement Fixation test for gonorrhea promises to be just as reliable as the Wassermann test for syphilis,

Therefore, Be It Resolved that the Women's Medical Association of New York City, lay

before the Women's Medical Society of New York State, the following motion requesting that they endorse it and in turn submit it to the House of Delegates of the Medical Society of New York State.

The motion is as follows

1 That the Complement Fixation Test for gonorrhea (comparable to the Wassermann blood test for syphilis) be standardized by the New York State Health Department and its values established.

2 That the enactment of a marriage law for New York State be urged which shall include,

(a) A suitable clinical examination and a blood Wassermann test (by a recognized laboratory) on both the male and female applicants

(b) A suitable clinical and laboratory examination for gonorrhea on both the male and female applicants

(c) That if the value of the Complement Fixation test for gonorrhea be established, this test shall also become compulsory

(d) That records of such examinations shall not become matters of public record, but shall remain confidential records under the Health Office of jurisdiction

(e) That the law shall not prohibit marriage of a person suffering from syphilis or gonorrhea, if proven non-infectious

(This motion was seconded and unanimously carried May 12, 1937 and Dr Emily Dunning Barringer, Chairman of the Legislative Committee, was authorized to present it to the Women's Medical Society of New York State at their annual meeting at Rochester)

THE SPEAKER Referred to Reference Committee on New Business C

66 Resolution Re Expressing appreciation for contributions to Medicine of the late John D Rockefeller

Section 77

DR. GROAT "*Resolved*, the Medical Society of the State of New York wishes to express to the family of the late John D Rockefeller its appreciation of his contributions to the promotion of scientific medicine throughout the world"

THE SPEAKER This resolution will be referred to Reference Committee on New Business D

67 Amendment to By-Laws re Component County Society Delegates

THE SPEAKER We have the following resolution "WHEREAS, the constitution and by-laws provide that each component county society shall be entitled to elect as many delegates as there shall be assembly districts in such county at the time of election, and

"WHEREAS, such representation is supposed to be based on population but in fact is not so based because of the failure of the State Legislature to make reapportionment, and

"WHEREAS, this Society should and can do away with political boundaries within the counties as far as it affects this body,

"Therefore, Be It Resolved, that each component county Society shall be entitled to elect at least one delegate, and one additional delegate for each 100,000 population as determined by the last United States census"

DR. KRAKOW, Bronx May I move the following substitution as an amendment

Each component county society shall be entitled to elect one delegate for each 100 members in such county at the time of election, but each component county society shall be entitled to elect at least one delegate. A component society representing by its name more than one county shall be entitled to a number of delegates proportionate to its combined membership at the rate of one delegate for one hundred members

THE SPEAKER This matter will lay over for one year

(Thereupon a recess was declared until 9 30 A.M. May 25, 1937)

ADJOURNED SESSION

May 25, 1937

The Speaker called the meeting to order at 9 30 A.M.

68 Report of Reference Committee on Report of Committee on Economics

DR. ROONEY Your Reference Committee wishes to commend the Committee on Economics for its assiduous devotion to its work during the past year. It has been instrumental in developing and nurturing an appreciation of the importance of economic factors in the practice of medicine and in bringing to the membership of the Society a knowledge of important trends in this phase of medical activity.

Your Reference Committee recommends the continued study of the many phases of the economics of medicine as developed by the Committee on Economics and in particular a more intensive and deeper study of the subject under consideration in their report, especially that devoted to medical indemnity plans.

Your Committee wishes to endorse the action of the Executive Committee of the Society taken on January 14, 1937, accepting the proposal of the Committee on Economics recommending the divorce or differentiation between Medical Service and Hospital Service, particularly in schemes like those of the Associated Hospital Service.

Your Reference Committee recommends the adoption of that part of the report of the Committee on Economics which states

"That it is the expressed opinion of the Medical Society of the State of New York that physicians practicing in groups, privately, or in hospitals should remain within the same

ethical framework as regards their conduct as though their activities were those of individual physicians"

Such a group should not obtain publicity by any means in lay publications, should not advertise, should not claim superior quality of service, and should not practice competitive fees against the individual doctors of the community. If the group relies solely upon the recognition of its services by the people as the means of acquisition of patronage it would be a proper and fair activity. On the other hand if the group, or hospital, by subterfuge, courts the patronage of the community by any form of publicity such physicians and the institution should be considered guilty of professional misconduct.

Your committee felicitates the Committee on Economics for its tact and good judgment in refraining, in accordance with the instructions of the House of Delegates, from issuing periodic bulletins and other similar publications during the past year.

Your Committee commends the Committee on Economics for the proposed review of its work during the past six years which is now in progress of preparation. This will be a great value to the Society and to others interested in the subject of medical economics.

Your Committee concurs in the report of the Committee on Economics condemning the practice of certain hospitals providing and advertising medical care to the public not entitled to free medical care for a fixed or advertised fee.

It reaffirms the recommendation of the Committee on Economics that medical care should be divorced and differentiated from hospital care or that service which the hospital may legitimately provide in assisting the medical profession to render proper medical care. Your Committee strongly recommends that such hospitals as are now participating in these practices of advertising or providing medical care under the above circumstances discontinue this practice as being beyond the function of the hospital per se and unfair to the medical profession.

Your Committee further recommends that hospitals should be bound by a code of ethics similar to those binding the medical members of their staffs, especially in regard to advertising and the solicitation of patronage.

It further recommends that participation by hospitals in such fixed fee medical service or other form of advertising or solicitation be construed as a violation of the principles of professional conduct and ethics.

Your Reference Committee feels that the Medical Society of the State of New York owes its gratitude to the Committee on Economics and particularly to its chairman, Frederick E. Elliott who has given unsparingly his ability and whole-hearted devotion to the welfare of the medical profession.

I move the adoption of the report of your Reference Committee as a whole.
(Motion seconded and carried)

69 Report of Reference Committee on Report of Committee on Legislation

See also Section 14

DR. HICKS Your Committee, having considered the report of the Legislative Committee, wishes to commend said committee for the work it has accomplished during the past year.

We concur in the attitude on the Basic Science Law. We concur with the view of the Legislative Committee on the referendum of the House of Delegates on withholding action at this time in regard to administration of anesthetics. In view of the fact that the Societies of Anesthetists are raising standards and fostering instruction in anesthesia, to supply the necessary number of trained medical anesthetists, it is deemed wise to wait until the societies of anesthetists feel that the demand of trained medical anesthetists can be fully met.

We approve the specific recommendations advertising to medical expense, indemnity insurance, and other health insurance proposals of your Legislative Committee. We recommend that the House of Delegates give due consideration to the growing interest in this matter.

We concur in the advisability of the Annual Meeting of the County Legislative Chairmen as recommended.

We concur in the issuance of the Legislative Bulletin and advise it be continued. We also advise that sufficient funds be allocated for this and other activities of your Legislative Committee in order that both public and medical interests be protected.

We recommend the proposal of negotiations between the State Bar Association and representatives of insurance carriers to bring about the passage of the Medical Lien Bill.

In spite of the approval of the Board of Regents for the bill introduced by the Osteopaths, the Legislative Committee was successful in defeating the bill on the floor of the Assembly.

Your Reference Committee is keenly conscious of the valuable work done both in this and previous years by our Legislative Committee and our executive officer.

The varied and varying members of our Legislative Committee have, under our old constitution and by-laws for more than a generation worked with tireless energy for the higher ideals of medical practice and the defeat of many proposed and vicious measures. It was a long tedious effort accompanied by many failures that gave to us our present medical practice act.

During all these years this committee has been classified by the corps legislative and lobbyists with what seems to us persistent inconsistency. Inconsistent, yes, for the term carries with it to the great world without, something that stands in the shadow of monopolistic corporative interests.

Your Committee makes this small gesture of appreciation both as a salutation and a requiem to the incoming and outgoing Committee on Legislation. In the name of the House of Delegates and the Medical Society of the State

of New York, we bid farewell to the outgoing and hail the incoming with all good wishes.

I move the adoption of this report.
(Motion seconded and carried.)

70 Report of Reference Committee on New Business B on resolution re Delegates to Connecticut and New Jersey Society Annual Meetings

Section 64

DR. MCGOLDRICK Reporting on the following resolution:

"WHEREAS, very cordial relations with the State Medical Societies of Connecticut and New Jersey have recently been established in connection with improving the Directory, and

"WHEREAS, the Connecticut State Medical Society asked that the Medical Society of the State of New York appoint two delegates to its annual meeting,

"Be It Resolved, that the Medical Society of the State of New York ask the State Societies of Connecticut and New Jersey to designate to its annual meetings two delegates hereafter, and

"Be It Further Resolved, that two delegates be appointed to the Connecticut State Medical Society."

Your Reference Committee recommends the approval of this resolution.

I move its adoption.

(Motion seconded and carried.)

71 Report of Reference Committee D on resolution re Radiology

Section 19

DR. MOTT This resolution, referred to Reference Committee D, was from the Special Committee on Radiology, New York County Medical Society.

The Medical Society of the State of New York has already established a section on radiology. In the opinion of the reference committee this constitutes recognition of the practice of diagnostic and therapeutic radiology, including the use of radium as a special branch of medicine.

Your reference committee therefore feels that the resolution as presented is superfluous.

I move the adoption of this report.

(Motion seconded and carried.)

72 Report of Reference Committee on New Business C on resolution presented by Women's Medical Society of New York State

Section 65

DR. HAMILTON Your Reference Committee on New Business C has carefully considered a resolution transmitted to the House of Delegates by the Women's Medical Society of the State of New York. Your Committee feels

that the subject matter transmitted in this resolution is one for mandatory legislation and public health education.

Legislation has already been introduced, but has never been enacted in this state. The medical profession and public health authorities recognize the fact that this procedure is the correct precaution for public health and happiness.

Your Committee feels that the education of the public by pamphlet, press, and radio is being, and should be, carried out by the Committee on Public Health of the Medical Society of the State of New York.

I move the adoption of this report.

(Motion seconded.)

DR. SCHIFF I would move to amend by referring this to the Council which will have a sub-committee on this topic.

DR. BARRINGER Members of the House of Delegates, as Chairman of the Legislative Committee of the Medical Association of Women in New York City, I was asked to carry this message to the State Meeting of the Women's Medical Society and then if it was passed there, to lay it before you for your very serious consideration.

I, therefore, am bringing you a message from the Medical Women of New York City and from the Medical Women of New York State. We feel that this matter is of paramount importance, but we have not yet been able to impress the medical public of that fact. Now, we wish to lay it before you gentlemen today and ask that it be given vigorous, scientific consideration. We want to have it go into a committee that will really evaluate it and let it have a practical outcome.

DR. KALISKI I believe we are all in sympathy with the Women's Medical Society, but this matter has been given serious consideration by a serious committee, a scientific committee of this Society. I feel that the resolution as referred to the Reference Committee, contains scientific statements that are open to question and I feel that the resolution, as offered should not be adopted by this House. It would take too long to refute some of the points made in the resolution. The resolution should be referred, in accordance with the amendment made by Dr Schiff, to the Council, or to a proper committee for further study.

THE SPEAKER I take it you are speaking in favor of the adoption of the amendment?

DR. KALISKI I am speaking in favor of the adoption of the amendment.

(A vote being taken, the motion amending the Report of the Reference Committee C was carried.)

73 Report of Reference Committee on New Business A, on resolution re The Kline-Todd Radiology Bill

Section 63

DR. CUNIFFE The following resolution was presented to your committee

'WHEREAS, radiologists through their organization, sponsored a bill in the 1937 New

York State Legislature known as the Kline-Todd Radiology Bill, and

"WHEREAS, such bill defined Radiology and proposed needed safeguards against the commercial exploitation of radiology, and

"WHEREAS, this bill was killed by the chairman of the Senate Committee who refused to report it out of committee,

"Therefore, Be It Resolved, that the Medical Society of the State of New York approve the principles of the Kline-Todd Radiology bill and direct the proper committee to re-introduce and support a similar measure at the 1938 New York State Legislature"

This bill defines the practice of radiology and restricts the use of the X-ray for diagnosis and treatment of disease to physicians. It protects the technician but he must be supervised by a member of the medical profession. On this account, the bill has been opposed by men outside of the profession who operate X-ray laboratories, and also by chiropractors. The committee approves the resolution asking that a similar bill be re-introduced into the 1938 State Legislature by our Legislative Committee.

I move the adoption of this report

(Motion seconded and carried.)

74 Report of Reference Committee on New Business D on resolution concerning employment of salaried physicians on contract by municipalities for medical service to home relief clients

Section 23

DR. MOTT The following resolution was presented to this committee

"WHEREAS, there is a strong tendency among public officials and welfare officers to favor the employment of physicians on salary to render medical service to welfare clients rather than to permit the patient to be attended by the physician of his choice with payment of the physician on a fee-for-service basis, and

"WHEREAS this manner of providing medical relief makes medical service for the poor a distinctly separate type of service from that available for those who are self-sustaining, constituting an intolerable discrimination against the unfortunate poor and denying them their elementary American right to choose their own medical attendants, and

"WHEREAS, such economies as may be claimed to result from such a contract system of medical relief are made possible only by exploitation of the physicians in a manner that must inevitably produce a sub-standard quality of service, and

"WHEREAS physicians serving under such contract systems are clearly violating the principle of medical ethics of the American Medical Association which forbid contracts where 'free choice of a physician is prevented' where 'compensation is inadequate to assure good medical service', or where 'there is interference with reasonable competition in a community', now,

"Therefore, Be It Resolved, that the Medical Society of the County of Westchester does hereby recommend that the Medical Society of the State of New York condemn the employment by municipalities of physicians on salary to attend home relief clients, and that the State Society sponsor legislation to amend section 84 of the Public Welfare Law in such a way as to require that medical relief be furnished by the physician of choice and compensated on a fee-for-service basis and to delete the present section enabling medical relief service by contract, and

"Be It Further Resolved, that the Medical Society of the State of New York sponsor such legislation as may be necessary to establish control over the medical aspects of medical relief service in the same way as the medical aspects of Workmen's Compensation Service are controlled"

Your Committee unanimously approves the resolution and recommends its adoption by the House of Delegates,

I so move

(Motion seconded and carried)

75 Report of Reference Committee A on resolution for memorial to A M A urging new policy for medical publicity

Section 24

DR. CUNNIFFE This resolution from the Westchester County Society reads

"Resolved, that the Medical Society of the County of Westchester does hereby memorialize the Medical Society of the State of New York recommending that it in turn immediately and urgently memorialize the American Medical Association, recommending that the American Medical Association establish a Department of Public Relations whose function it shall be to engage the most expert and talented professional public relations counsel available, this Department of Public Relations to be equipped at once with adequate financial resources to carry on a permanent campaign of publicity and advertising through the most obvious media reaching the masses of public opinion and setting forth dramatically and accurately, the story of medical progress in the United States revealing and explaining the foundations of future progress and creating an informed public will to preserve those foundations, and be it further

"Resolved, that this resolution be introduced in the House of Delegates of the Medical Society of the State of New York at the meeting of the House, May 24, 1937"

The Committee is informed by the counsel of the Society that the carrying out of the provisions of this resolution would make the American Medical Association subject to Income Tax. The Committee therefore disapproves of the resolution

I move the adoption of this report.
(Motion seconded and carried)

76 Report of Reference Committee D on New Business re Automobile License Plates

Section 30

DR. MOTT The following resolution was presented to your committee

"WHEREAS, it is the policy of the Motor Vehicle Department of the State of New York to issue distinctive license plates to members of various fraternal, social and civic groups, as may be noted by the numerous plates seen with different combinations of letters before the numbers, as ST—, AL—, QS—, AY—, and others, and

"WHEREAS there are registered, as members of the Medical Society of the State of New York, the total of 14,194 physicians for the year 1936,

"Therefore, Be It Resolved, that the Medical Society of the State of New York petition the Motor Vehicle Department of the State of New York to issue special and distinctive license plates to physicians, in good standing and registered with the Medical Society of the State of New York, these plates to bear the letters "MD" or "DR", followed by the proper numbers, and

"Be It Further Resolved, that not more than one set of license plates bearing these letters shall be issued to one physician and that for use on his professional car, and

"Be It Further Resolved, that the application for special plates shall be approved by the secretary of the County Medical Society of which the applicant is a member"

Your committee recommends that these resolutions be disapproved

I so move

(Motion seconded)

DR. KALISKI In New York we have been trying to obtain special license plates for physicians in view of the critical traffic situation in the metropolitan area. I think it would be very useful if the House were to go on record as favoring this resolution. We have already taken steps to urge the Motor Vehicle Commissioner to do this and I believe the recommendation by this House would greatly help in bringing that about.

DR. SCHIFF I offer a substitute motion before the House, that this House endorse the substance of the resolution offered

(Motion seconded and carried)

77 Report of Reference Committee D on New Business, on resolution re John D Rockefeller contributions to medicine

Section 66

DR. MOTT The following resolution was handed to your Reference Committee

"Resolved That the Medical Society of the State of New York wishes to express to the family of the late John D Rockefeller its

appreciation of his contribution to the promotion of scientific medicine throughout the world"

We approve the resolution and move its adoption.

DR. SCHIFF I would like to move to amend so that the resolution includes the phrase "medical education" after the words "scientific medicine."

(Motion seconded and carried.)

DR. SCHIFF I would further like to amend that a copy be sent to the family and the various foundations and other philanthropic enterprises of the late Mr. Rockefeller

(Motion seconded and carried.)

THE SPEAKER The resolution now reads

"Resolved, that the Medical Society of the State of New York wishes to express to the family of the late John D. Rockefeller its appreciation of his contribution to the promotion of scientific medicine and medical education throughout the world, and that the various foundations and other philanthropic enterprises of the late Mr. Rockefeller be notified of this action."

78 Report of Reference Committee on the report of the Committee on Public Health and Medical Education

See also Section 11

DR. BRITAIN The Reference Committee for consideration of the report of the Committee on Public Health and Medical Education for the past year feels that our wisest plan is to continue as far as possible its recommendations and suggestions. The chairman of this committee, Dr. Farmer, is a man who from his associations with this body and his years of experience in the management and direction of the various health activities makes him peculiarly fitted to be continued as the chairman of this committee and no better complement could be paid Dr. Farmer, than to approve and further the plans of his committee

Pneumonia

The work of Dr. Farmer's committee on the subject of pneumonia control commands the highest praise and approval. The able review of this subject in the February 1937 issue of the New York Academy of Medicine's publication "Preventive Medicine" by Dr. Peter Irving, Dr. Rufus Cole's survey of the Public Health problem in the *American Journal of Public Health* and the numerous articles as appearing in the NEW YORK STATE JOURNAL OF MEDICINE, and the *Journal of the A.M.A.* are other publications stressing the importance of the serum therapy as the only specific and rational method of combatting this disease, especially types I and II pneumonia.

The fine cooperation of our state association with the public health authorities and private foundations working for a common cause and for the public welfare is especially worthy of

note. That the initiative for this work came from our own State Society through Dr. Farmer's able direction and that of his committee, is to the lasting credit of organized medicine in this state. We should energetically improve and encourage work of this kind without stint and lend our support earnestly to further the expansion of this life saving work. Of especial commendation in this respect is the chairman's successful efforts in securing the appropriation of \$400,000 by the last legislature to further the manufacture and distribution of this serum to all the physicians of the state.

Cancer Control

Dr. Farmer in his supplementary report on the subject of cancer control has urged that the commission recently appointed by the legislature for the study of this problem in addition to the members from the Senate and Assembly and the State Commissioners of Health should include representative medical men and the setup for the work should be similar to the method used in the pneumonia control and syphilis problem. This work has been well-handled by a Joint-Advisory Committee composed of members of the medical profession and health groups.

The Reference Committee recommends the adoption of the following resolutions submitted in the supplementary report

"WHEREAS, motion picture films are being offered both free of charge and on a rental basis by organizations, commercial and non-commercial, for programs of county medical societies, and in some instances with speakers, and

"WHEREAS, some of these motion picture films carry advertising matter or propaganda to which objection might be raised,

"Be It Resolved, that the House of Delegates of the Medical Society of the State of New York, in annual session convened at Rochester, New York, this 24th day of May, 1937, request the House of Delegates of the American Medical Association to make provision for the review and classification of films and other similar material offered for programs of county medical societies, so that information regarding them may be available to County Medical Societies

"Be It Further Resolved that the delegates from New York State to the annual meeting of the American Medical Association at Atlantic City, on June 7, 1937 be instructed to present and to further the passage of the foregoing resolution"

We move the adoption of these resolutions (Motion seconded and carried.)

DR. BRITAIN In view of the fact that the program of the Committee on Public Health and Medical Education includes activities that will not be completed until July 1, and if the revision of the constitution and by-laws is adopted at the present meeting the Reference Committee recommends that the chairman of the Committee on Public Health and Medical

Education be empowered to complete the unfinished portions of the current program up to July 1, 1937

(Motion seconded and carried)

DR WIGHTMAN This meeting has been so great a success under Dr Winslow that I move you an appreciative vote on the part of this Assembly thanking him for the success of this meeting

(Motion seconded and carried)

79 Testimonial to Miss Baldwin

DR ROONEY Miss Baldwin has been retired. I hope the Society will never lose the service of her advice. She is going to have an engrossed piece of paper to hang on the wall but we feel we would like to have something a little more substantial that she could have with her all the time to remind her of the affection in which she is held by this House and by the representatives of this Society. Dr Emily Barringer has suggested that we take up a subscription and appoint a committee to purchase some memento such as a pin or whatever the committee decides upon that she may have as a constant reminder of the devotion and affection in which she is held by us.

I move that the Speaker be empowered to appoint a committee of three to take up a subscription from this House for the purchase of a suitable memento to be given to Miss Baldwin

(Motion seconded and carried.)

THE SPEAKER It gives me pleasure to act. I appoint Dr Barringer, *Chairman*, Dr Bedell and Dr Van Etten

DR KOSMAK Before we adjourn it seems to me appropriate for this House of Delegates to extend to the City of Rochester an expression of its appreciation for all that the Chamber of Commerce and other organizations of this community have done to make the Rochester meeting of this Society the great success that it is. I move you, sir, that an appropriate expression of this type be forwarded to these people by the secretary of the Society.

DR BEDELL I would like to amend the motion to particularly mention Dr Simpson

DR KOSMAK I accept.

(Motion seconded and carried.)

80 Elections

Section 82

THE SPEAKER We will now proceed to the election of officers. The secretary will call the roll of the individual delegates by counties.

The Assistant Secretary called the roll and the following Delegates responded.

Frederic C Conway, William P Howard, John J Clemmer, Jr., Lyman C Lewis, J Lewis Amster, Thomas J O'Kane, Edward R. Cunniffe, Vincent S Hayward, Jacob A Keller, William Klein, Moses H Krakow, Solomon Krell, Samuel M Allerton, George C. Vogt,

Leo E Reimann, Harry S Bull, Edgar Bieber, De Forest W Buckmaster, Reeve B Howland, Ralph H Loomis, Leo F Schiff, Daniel R. Reilly, Robert Brittain, C Knight Deyo, Aaron Sobel, Herbert H Bauckus, James H Borrell, Harvey P Hoffman, James Herbert Donnelly, Albert A Gartner, Harry C Guess, Thurber Le Win, Joseph C O'Gorman, Daniel C Munro, Sylvester C Clemans, Peter J Di Natale, Jere J McEvilly, Charles A. Prudhon, Charles A. Anderson, Albert F R. Andresen, Robert F Barber, John L Bauer, Thomas M Brennan, William Rachlin, John B D'Albora, Maurice J Dattelbaum, Benjamin Davidson, Harry Feldman, Samuel S Fischhoff, Simon Frucht, Edwin A. Griffin, Henry Joachim, Walter D Ludlum, Thomas A. McGoldrick, John J Masterson, William E. Lippold, Joseph Raphael, J Sturdivant Read, Nunzio A. Rini, Irving J Sands, Augustus Harris, F Edward Jones, Judson M Burt, Anthony J Zaia, Clarence V Costello, William A MacVay, Willard H Veeder, Edward T Wentworth, Warren Wooden, Horace M Hicks, Louis H Bauer, George A Newton, Walter P Anderton, Clarence G Bandler, Emily D Barringer, Conrad Berens, Edward C. Brenner, Samuel B Burk, J Homer Cudmore, Adolph G DeSanctis, Julius Ferber, B Wallace Hamilton, Benjamin Jablons, David J Kaliski, Frederick C Keller, J Stanley Kenney, Moses Keschner, Francis N Kimball, Richard Kovacs, Oscar L Levin, James Alexander Miller, Peter M Murray, William M Patterson, Nathan Ratnoff, Louis C Schroeder, William A Peart, Richard H Sherwood, William Hale, Jr., Edward E Powers, Andrew Sloan, John J Buettner, William W Street, Albert G Swift, Homer J Knickerbocker, M Renfrew Bradner, Moses A Stivers, Arthur I Eccleston, Ross F Wolever, Floyd J Atwell, Henry W Miller, James M Dobbins, W Guernsey Frey, Jr., Frank R Mazzola, H P Mencken, James R. Reuling, Jr., Joseph Wrana, John D Carroll, William B D Van Auker, Arthur S Driscoll, Stanley C Pettit, Stephen R. Monteith, W Grant Cooper, Robert J Reynolds, George S Towne, Frank L Sullivan, William C Treder, David W Beard, Edward M Wellbery, Glenn L Whiting, Herbert B Smith, Coburn A L. Campbell, John L Sengstack, Irving Greenberg, Arthur C Hartnagel, Norman S Moore, Frederic W Holcomb, Morris Maslon, Denver M Vickers, Ralph Sheldon, Robert B Hammond, Arthur F Heyl, Merwin E Marsland, Walter W Mott, Romeo Roberto, Louis L Klostermyer, Bernard S Strait

The following Officers were present: Floyd S Winslow, Charles H Goodrich, Guy S Carpenter, Moses A Stivers, Peter Irving, Edward C Podvin, George W Kosmak, Aaron Sobel, Samuel J Kopetzky, James M Flynn, James F Rooney, George W Cottis, Nathan B Van Etten, James E Sadlier, Harry R. Trick, Thomas P Farmer, Homer L Nelms, Frederic E Elliott, Augustus J Hambrook, William A Groat, Leo F Simpson, Terry M Townsend, Carl Boettiger, Bertran W Gifford, Leo P Larkin, Thomas W Maloney, H Wolcott Ingham

The following Ex-Presidents were present
 Martin B Tinker, Grant C Madill, James F
 Rooney, Arthur W Booth, Orrin Sage Wight-
 man, Nathan B Van Etten, George M Fisher,
 James E. Sadlier, Harry R. Trick, William H
 Ross, William D Johnson, Chas Gordon Heyd,
 Frederick H Flaherty, Arthur J Bedell, Fred-
 eric E. Sondern, Allen A Jones

81 Tellers

THE SPEAKER There is a quorum present
 and we can proceed with the election The
 Speaker announces the following tellers

Frederic C Conway	Albany
John J Masterson	Kings
Adolph G DeSanctis	New York
George S Towne	Saratoga
Aaron Sobel	Dutchess
Harry C. Guess	Eric

In the nominations for the position of first
 Vice-President, the same individual under the
 new Constitution is the president-elect, so when
 you nominate for first Vice-President, you
 are, in fact also nominating for president-elect.

In regard to the nominations for the nine
 Councilors, to facilitate matters and with your
 gracious permission, the three having the
 largest number of votes will be considered as
 elected for the longest term, the next three
 for the next longest term, and the last three
 receiving the highest votes for the one-year
 term.

82 Election of Officers

Section 80

The following Officers were elected

President-Elect and First Vice-President, WIL-
 LIAM A. GROAT, Syracuse

Second Vice-President, ARTHUR S DRISCOLL,
 St. George

Secretary, PETER IRVING, New York

Assistant-Secretary, EDWARD C PODVIN, Bronx

Treasurer, GEORGE W KOSMAK, New York

Assistant Treasurer, AARON SOBEL, Pough-
 keepsie

Speaker, SAMUEL J KOPETZKY, New York

Vice-Speaker, JAMES M FLYNN, Rochester

Trustee five-year term, JAMES F ROONEY,
 Albany

Trustee, Wm H Ross, Brentwood

Councilors, three-year term terminating 1940

THOMAS P FARMER, Syracuse

JAMES H BORRELL, Buffalo

AUGUSTUS J HAMBROOK, Troy

Councilors, two-year term terminating 1939

EDWARD T WENTWORTH, Rochester

OLIVER W H MITCHELL, Syracuse

THOMAS H. CUNNINGHAM, Glens Falls

Councilors, one-year term terminating 1938

JOHN J MASTERSON, Brooklyn

GUY S CARPENTER, Waverly

FREDERIC E ELLIOTT, Brooklyn

83 A.M.A Delegates

The following were elected for 1937-38

SAMUEL J KOPETZKY

FREDERIC E SONDERN

JAMES M FLYNN

THOMAS A. MCGOLDRICK

CHARLES H GOODRICH

GEORGE M FISHER

PETER IRVING

The following were elected Alternates for
 1937-38

EDWARD C PODVIN

ADOLPH G DESANCTIS

FLOYD J ATWELL

JAMES R. REULING

CARL BOETTIGER

JOHN BAUER (Kings)

L H BAUER (Nassau)

DR. SONDERN Many have labored hard and
 long in, or in connection with this association,
 but I believe that Dr Mitchell's Committee on
 the Revision has put in more time and effort,
 probably, than any other individual or group
 and I think they deserve a mark of apprecia-
 tion and, Mr Speaker, I so move.

(Motion seconded and carried)

DR. BEDELL I move that this House of Dele-
 gates extend its thanks to the Rochester Cham-
 ber of Commerce for having turned this build-
 ing over to the Medical Society of the State
 of New York for the entire week for the
 purpose of holding its 131st Annual Convention
 (Motion seconded and carried)

DR. ROONEY I move you, sir, that the
 Speaker appoint a committee to draw up an
 appropriate memoriam concerning the death
 of Dr James N VanderVeer, a former presi-
 dent and Dr George Leitner of Nvack

(Motion seconded and carried)

THE SPEAKER Is there any further business
 before this House?

(On motion seconded and carried the House
 adjourned sine die.)

SAMUEL J KOPETZKY, *Speaker*

PETET IRVING, *Secretary*

LEGISLATIVE BUREAU

Final Bulletin

June 7, 1937

The Governor's thirty-day period is now completed and we are pleased to submit this final report on the bills that we have been following during the year. We are certain you will agree with us that the year has been an exceedingly busy one and that we have fared remarkably well considering the serious bills that threatened our welfare from time to time. Our success was not a happenstance, but the result of very hard work, in which we acknowledge receiving most effective and enthusiastic support not only from every county chairman but from many of those who are simply bulletin readers. We must also not forget the harmonious relationships that Dr. Lawrence developed with the legislators. One of the happiest recollections of this year's work probably will be that when bills in which we were interested were debated in either chamber of the Legislature, the debaters did not indulge in tirades against the medical profession, but, on the contrary, constructively debated the proposed measures and in a number of instances, outstanding among them being the debate on our lien bill, pointed out unsuspected weaknesses of the bill. All of the measures that we approved and were passed by the Legislature, were also approved by the Governor. May we suggest that if you share our feelings of gratitude toward the Governor and the legislators, that in an appropriate manner you let them know of it.

* * *

Senate Int. 1—social security—Chapter 15 of the Laws of 1937

Senate Int. 21, Assembly Int. 188—social security—defeated in Assembly Rules Committee

Senate Int. 47—Workmen's Compensation Law, awards—defeated in committee

Senate Int. 55, Assembly Int. 230—shipment of milk and cream into State—defeated in Senate Health Committee

Senate Int. 58, Assembly Int. 156—appropriation to pay indemnities for bovine animals killed on account of mastitis—defeated in committee

Senate Int. 59—for testing bovine animals for infectious diseases—defeated in committee.

Senate Int. 67—establishing narcotic control bureau in Department of Health—Chapter 914 of the Laws of 1937

Senate Int. 173—testimony by deposition—defeated in committee

Senate Int 594, Assembly Int 928—creating consumers' bureau in Department of Health—defeated in committee

Senate Int 598—advertising by physicians—lost on second reading

Senate Int 600—nurse practice—defeated in committee

Senate Int. 613, Assembly Int 575—compelling immediate report by physician examining specimen disclosing communicable disease if results obtained are needed for purpose of release from quarantine or observation—Chapter 414 of the Laws of 1937

Senate Int 614—registration of births within 48 hours—lost on second reading

Senate Int 615, Assembly Int 299—prohibiting persons other than licensed physicians, dentists and veterinarians to possess or cultivate live pathogenic microorganisms or viruses without permit from Health Commissioner—Chapter 412 of the Laws of 1937

Senate Int 618, Assembly Int. 573—prohibiting possession, dispensing or sale after July 1, 1937, by a dispensary, without approval of Health Department, of any narcotic preparation described in section 428 of the Health Law—Chapter 413 of the Laws of 1937

Senate Int 666—indigent inmates of State tuberculosis hospitals to be cared for by State instead of county—defeated in committee

Senate Int. 669, Assembly Int 900—for regulation of practice of optician—lost on third reading

Senate Int 672—Workmen's Compensation Law, defining "occupational disease"—defeated in committee

Senate Int. 683, Assembly Int 471—for issuing permanent injunction against illegal practice of a profession—defeated in committee

Senate Int. 737—defining "home relief" to include drugs, medicines, etc., and relative to reimbursement for home relief and its administration—Chapter 358 of the Laws of 1937

Senate Int. 745, Assembly Int. 925—requiring public welfare officials to provide medical care for sick persons in homes when necessary, physician to be family physician—defeated in committee

Senate Int 746, Assembly Int. 1051—relative to establishment of State cancer hospitals—defeated in committee

Senate Int 755, Assembly Int. 346—changing designation of Social Hygiene Division to that of Syphilis Control—Chapter 395 of the Laws of 1937

Senate Int. 811, Assembly Int 1216—

regulating practice of hairdressing and cosmetology—vetoed

Senate Int 838—making municipalities liable for malpractice of physicians and dentists rendering gratuitous services to public institutions—Chapter 483 of the Laws of 1937

Senate Int 855—indigent inmates of State tuberculosis hospitals to be cared for by State instead of county—defeated in committee

Senate Int 876, Assembly Int. 1291—providing for class "A" multiple dwellings for hospital personnel, nurses, etc.—defeated in Senate New York City Committee

Senate Int. 915, Assembly Int. 1319—physicians' lien—lost on third reading

Senate Int 999, Assembly Int. 1308—requiring State to pay cost of maintaining indigent patients in State tuberculosis hospitals—lost on third reading

Senate Int. 1001, Assembly Int 1450—requiring State to reimburse public welfare district to extent of one-half of amount expended for medical attention and hospital care—defeated in committee.

Senate Int 1024, Assembly Int. 1514—making town responsible for home relief and medical care of defective and physically-handicapped and illegitimate children, and authorizing care of illegitimate child and mother at free boarding home or institution—Chapter 411 of the Laws of 1937

Senate Int. 1041, Assembly Int 1389—relative to coloring and labeling of food products—defeated in Assembly Rules Committee

Senate Int 1089, Assembly Int. 1487—requiring certification of qualified psychologists—lost on third reading

Senate Int. 1118, Assembly Int 1573—nurse practice—defeated in committee

Senate Int 1174, Assembly Int 1322—creating board of beauty culture in Department of Health—defeated in committee

Senate Int. 1223, Assembly Int 1672—creating New York State Mineral Springs Authority and abolishing Saratoga Springs Commission—defeated in Senate Finance Committee

Senate Int. 1228—providing hospital care and treatment for volunteer firemen injured in performance of duty—defeated in Assembly Rules Committee

Senate Int. 1317, Assembly Int 1950—practice of radiology—died on third reading

Senate Int. 1368—requiring domestic servants to furnish health certificate showing freedom from communicable or contagious disease—lost on third reading

Senate Int. 1369, Assembly Int 1605—

practice of osteopathy—defeated on Assembly floor

Senate Int. 1392, Assembly Int. 1603—appropriating \$1,000,000 as revolving fund in Department of Health for pneumonia serum—defeated in committee.

Senate Int. 1418, Assembly Int. 1325—permitting trustee or member of education board of school district to be employed as medical inspector provided he is the only qualified physician residing therein—vetoed.

Senate Int. 1444, Assembly Int. 2359—Workmen's Compensation Law, defining powers and duties of Industrial Board, etc.—defeated in committee

Senate Int. 1488, Assembly Int. 2054—providing for three optional plans for organization of county welfare departments—lost on third reading

Senate Int. 1538, Assembly Int. 1904—for regulation of practice of dispensing optician—defeated in committee

Senate Int. 1547—to provide for instruction of children with defective hearing in city and union free school districts, and appropriating \$600,000—defeated in committee.

Senate Int. 1551, Assembly Int. 2121—providing that when patients in state tuberculosis hospitals have no legal settlement, there care and treatment shall be paid by State—defeated in Senate Health Committee.

Senate Int. 1558, Assembly Int. 2115—Workmen's Compensation Law, relative to awards to owner of medical bureau or laboratory—defeated in Assembly Rules Committee.

Senate Int. 1653, Assembly Int. 2268—nurse practice—defeated in committee

Senate Int. 1654, Assembly Int. 2270—nurse practice defeated in committee.

Senate Int. 1700, Assembly Int. 2291—relative to care of the blind, to make commission responsible for hospitalization and special nursing care in indigent cases of ophthalmia neonatorum—defeated in Assembly Rules Committee.

Senate Int. 1744—nurse practice—defeated in committee

Senate Int. 1749, Assembly Int. 2312—relative to suppression of rabies in Westchester County—Chapter 649 of the Laws of 1937

Senate Int. 1806—practice of physiotherapy—defeated in Assembly Rules Committee.

Senate Int. 1851—providing for medical inspection of all school children—defeated in Assembly Rules Committee.

Senate Int. 1865—advertising by podiatrists—defeated in committee

Senate Int. 1904, Assembly Int. 2437—appropriating \$400,000 to the Department of Health for prevention, diagnosis, treatment, and control of pneumonia—Chapter 259 of the Laws of 1937

Senate Int. 1928—relative to instruction of deaf—Chapter 439 of the Laws of 1937

Senate Int. 1944—for formation of consumers' cooperative non-stock corporations for furnishing medical care—defeated in committee

Senate Int. 1945—Greater New York Charter, relative to deputy medical examiners—defeated in committee

Senate Int. 1962—Workmen's Compensation Law, relative to laboratories, medical treatment, and hospital charges—defeated in committee

Senate Int. 2027—creating commission to examine and recommend measures to improve facilities for care of hard of hearing and deaf children—Chapter 743 of the Laws of 1937

Senate Int. 2033—requiring sanitary toilet and lavatory facilities in hotels, restaurants, etc.—defeated in committee.

Senate Int. 2118—exempting physician from speed and parking restrictions while attending patient on an emergency call—lost on third reading

Assembly Int. 1—for testing bovine animals for Bang's and other infectious diseases—lost on third reading in Senate.

Assembly Int. 59—to permit old age pension recipients to have medical care in hospital or sanitarium—defeated in committee

Assembly Int. 106—social security—defeated in committee.

Assembly Int. 179, 642, 788, 813—making Department of Health agency for administering certain parts of Social Security Act—defeated in committee

Assembly Int. 196—testimony, by deposition—defeated in committee

Assembly Int. 260—for care of indigent persons suffering from motor vehicle injuries—defeated in committee

Assembly Int. 298—striking out provision exempting first-class cities from requirement for medical inspection of pupils—defeated in committee.

Assembly Int. 311—creating commission to study causes, etc. of juvenile delinquency—defeated in Rules Committee

Assembly Int. 312—for licensing clinical laboratory technicians—defeated in committee

Assembly Int. 327—marriage licenses, blood tests—defeated in committee

Assembly Int. 335—Workmen's Compensation Law, physical examination of employees—defeated in committee

Assembly Int. 355—marriage licenses, blood tests—defeated in committee

Assembly Int. 365—authorizes cities in State to establish summer vacation camps for children in parks adjacent to city and under control of State Council of Parks and appropriate necessary monies, no child to receive free instruction in excess of two weeks—Chapter 791 of the Laws of 1937

Assembly Int. 370—nurse practice—defeated in committee

Assembly Int. 423—authorizes New York City to establish summer vacation school camps for children in parks adjacent to city and under control of State Council of Parks, where study courses not exceeding ten hours a week shall be given in camp sanitation, elementary hygiene, first-aid to injured, life saving, swimming, and physical training, and authorizing City to appropriate such sums as may be necessary—Chapter 792 of the Laws of 1937

Assembly Int. 476—operators of motor vehicles, eye and hearing tests—defeated in committee

Assembly Int. 485—food handlers, health certificates—defeated in committee

Assembly Int. 503—maternity subsidy—defeated in Senate Cities Committee

Assembly Int. 513—hospital employees, hours of labor—defeated in committee

Assembly Int. 571—creates commission to study health and living conditions, etc., of urban colored population—Chapter 858 of the Laws of 1937

Assembly Int. 574—relative to issuance of certified copies of birth and death certificates—Chapter 391 of the Laws of 1937

Assembly Int. 702—relative to dental inspection of school children—defeated in committee

Assembly Int. 804—for licensing clinical laboratory technicians—defeated in committee

Assembly Int. 892—compulsory health insurance—defeated in committee.

Assembly Int. 922—definition of "chemist"—defeated in committee

Assembly Int. 934—advertising by physicians—defeated in committee

Assembly Int. 942—nurse practice—defeated

Assembly Int. 1133—amending Public Welfare Law generally—defeated in Rules Committee.

Assembly Int. 1148—requiring State to pay cost of maintaining indigent patients in State tuberculosis hospitals—defeated on floor

Assembly Int. 1167—physicians, malpractice, public institutions—defeated in committee. (See Senate Int. 838)

Assembly Int. 1179—definition of "occupational disease"—lost on third reading

Assembly Int. 1285—antivivisection—defeated in committee

Assembly Int. 1386—birth certificates, fingerprints and footprints—defeated in committee.

Assembly Int. 1399—for creation of consumers' bureau in Department of Health—defeated in committee.

Assembly Int. 1558—amendment to Hospital Lien Law enacted in 1936—lost on third reading

Assembly Int. 1585—licensing roadside cottages—defeated in committee

Assembly Int. 1650—central bureau of hospital clinics—defeated in Rules Committee

Assembly Int. 1657—Greater New York Charter, supervision of health conditions on all transit lines, etc—defeated in Rules Committee

Assembly Int. 1675—injured volunteer firemen, hospital care—defeated in committee.

Assembly Int. 1817—appropriating \$300,000 to Agriculture Department for payment of indemnities on account of bovine tuberculosis and Bang's disease—Chapter 746 of the Laws of 1937

Assembly Int. 1901—antivaccination—defeated in committee

Assembly Int. 1907—for establishment of cancer hospital sites and hospitals—defeated in committee

Assembly Int. 1995—requiring State to pay cost of maintaining indigent patients in State tuberculosis hospitals—defeated in committee

Assembly Int. 1998—indigent patients, State tuberculosis hospitals—defeated in committee

Assembly Int. 2002—creating temporary commission to consist of Health Commissioner, ex-officio, two other resident physicians appointed by Governor, three members of Assembly and three Senators, to study existing facilities for treatment and prevention of cancer and care of persons afflicted, and any other pertinent facts relating thereto, and appropriating \$15,000—Chapter 718 of the Laws of 1937

Assembly Int. 2134—nurse practice—defeated in Rules Committee

Assembly Int. 2248—Criminal Code, permitting serologic blood test to determine parentage of child, etc—defeated in Senate Codes Committee

Assembly Int. 2281—labeling of food and food products—defeated in Rules Committee.

Assembly Int. 2360—Workmen's Compensation Law, relative to medical bureaus and laboratories and payment of bills for medical care—defeated in Rules Committee
 Assembly Int. 2519—Vehicle and Traffic

Law, requiring examination by physician of person suspected of being intoxicated while driving a motor vehicle—defeated in Rules Committee

COMMITTEE ON LEGISLATION

AMERICAN BOARD OF SURGERY

In answer to the widespread demand for an agency which will attempt to certify competent surgeons the American Board of Surgery has recently been organized. This Board is a member of the Advisory Board of Medical Specialties which includes all of the boards of certification for the different medical specialties which have been already organized. Since boards were in existence for the certification of practitioners of some of the surgical specialties such as ophthalmology, otolaryngology, obstetrics and gynecology, genito-urinary surgery and orthopedic surgery it is expected that the American Board of Surgery will be responsible for the certification of general surgeons as well as those practicing in the remaining specialized subdivisions of surgery.

Acting upon the invitation of the American Surgical Association the following surgical societies cooperated in the creation of the American Board of Surgery: the American Surgical Association, the Surgical Section of the American Medical Association, the American College of Surgeons, the Southern Surgical Association, the Western Surgical Association, the Pacific Coast Surgical Association and the New England Surgical Society. The first three of these bodies which are national in scope have three representatives on the Board. All of the other societies have one representative each. The representatives of the cooperating societies are nominated by the society which they represent and upon approval of the Board shall become members of it. The term of membership on the Board will be six years. The following were chosen to represent the cooperating surgical societies:

Dr. Everts A. Graham, Dr. Arthur W. Elting, and Dr. Allen O. Whipple—representing the American Surgical Association
 Dr. Donald Guthrie, Dr. Erwin R. Schmidt and Dr. Harvey B. Stone—representing the American College of Surgeons
 Dr. Fred W. Rankin, Dr. Howard M. Clute and Dr. J. Stewart Rodman—representing the Surgical Section of the A.M.A.
 Dr. Philemon E. Truesdale—representing the New England Surgical Society
 Dr. Thomas Orr—representing the Western Surgical Association

Dr. Robert Payne—representing the Southern Surgical Association

Dr. Thomas Joyce—representing the Pacific Coast Surgical Association

The following officers were elected

Chairman—Dr. Everts A. Graham

Vice-Chairman—Dr. Allen O. Whipple

Secretary-Treasurer—Dr. J. Stewart Rodman

Two groups of candidates are recognized for qualification by the Board. (A) Those who have already amply demonstrated their fitness as trained specialists in surgery. (B) Those who, having met the general and special requirements exacted by the Board, successfully pass its qualifying examination.

The first of these groups, the Founders Group, upon invitation by the Board will be chosen from the following: (1) Professors and Associate Professors of Surgery in approved medical schools in the United States and Canada. (2) Those who for fifteen years prior to the Board's organization have limited their practice to surgery. (3) Members of the American Surgical Association, the Southern Surgical Association, the Western Surgical Association, the Pacific Coast Surgical Association and the New England Surgical Society, who are in good standing January 9, 1937.

All applications for the Founders Group must be received within two years of the Board's organization January 9, 1937. No candidates for the Founders Group will be considered after that date.

Requirements for those to be qualified by examination will be as follows: (1) Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the A.M.A. or graduation from an approved foreign school. (2) Completion of an internship of not less than one year in a hospital approved by the same Council or its equivalent in the opinion of the Board. (3) *Special Training*. A further period of graduate work of not less than three years devoted to surgery taken in a recognized graduate school of medicine or in a hospital or under the sponsorship accredited by the American Board of

Assembly Int 355—marriage licenses, blood tests—defeated in committee

Medical News

Albany County

RESIGNATION OF Dr Thomas Ordway, dean of Albany Medical college for twenty-two years, has been announced. He will remain as professor of medicine and will practice in Albany. Dr Robert Sydney Cunningham of Vanderbilt Medical school has been appointed professor of anatomy, and will succeed Dr Ordway as dean. Dr John A Sampson, chairman of the department of gynecology and obstetrics, and Dr Arthur W Elting, professor of surgery, also retired from the college staff July 1. Dr Sampson will continue with the college as Alden March professor of gynecology and obstetrics. Both have reached the statutory age limit.

DR ARTHUR J BEDELL Albany eye surgeon, sailed on the *Aquitania* June 30 to speak and show motion pictures before the Oxford Ophthalmological Congress July 8, 9, and 10.

Dr Bedell last year addressed the British Medical Association meeting at Oxford, England, and showed motion pictures of the interior of the eye.

After the Oxford meeting Dr Bedell will tour England and possibly visit Sweden, returning home late in August.

Broome County

A JOINT MEETING of the Broome County Medical Society, Binghamton Academy of Medicine, Endicott Johnson Medical Society, and Binghamton Psychiatric Society, was held on June 1. Dr Richard Kovacs of New York City spoke on "The Role of Physiotherapy in the Treatment of Nervous and Mental Disease."

Dutchess County

THE ANNUAL OUTING of the Dutchess County Medical society was held on June 2 at the Harlem Valley State hospital. Ferdinand A White spoke on "Workmen's Compensation Problems" at a dinner in the hospital dining hall.

Erle County

DR CARLTON R JEWETT, who had practiced medicine for forty years in Buffalo before he retired in 1922, died at his home on May 20 in his eighty-sixth year.

Livingston County

DR CHARLES VERNON PATCHIN, who died on May 30 at the age of eighty-three, had practiced medicine in Dansville fifty-six years. He retired as village health officer in 1926 after forty years' service. He was state sanitary supervisor for Livingston, Wyoming, Genesee, Monroe, Ontario and Wayne counties in 1914-15-16 and 17.

New York County

DR RUFUS COLE, head of the hospital department of the Rockefeller Institute for Medical Research, retired on June 30, the institute's board of scientific directors has announced. He had been director since 1910.

Dr Cole reached the retirement age of 65 on April 30. He was succeeded by Dr Thomas Milton Rivers, also a member of the institute's staff.

Dr Rivers is 58, a native of Georgia and graduate in medicine of Johns Hopkins University. He was appointed to membership in the Rockefeller Institute ten years ago after having met Dr Cole during the World War. At the close of the war Dr Rivers conducted studies of influenza bacilli at Johns Hopkins which resulted in the discovery of a new bacterium, *homophilus parainfluenzae*. At the Institute Dr Rivers investigated filterable viruses which led to the discovery of a vaccine for the prevention of small pox. He also developed a safe method of diagnosing parrot fever.

Dr Cole directed the energies of the hospital toward the study of common diseases which affect large numbers of persons, especially acute respiratory diseases, rheumatic fever and diseases of the heart. As a result of his work great strides were made in better understanding of pneumonia.

THE ITALO-AMERICAN Medical Association was organized on May 25, in the Parkway Hospital, 123 West 110th street Manhattan. Active membership is limited to Italian-Americans who have completed their pre-medical studies in the United States and have subsequently been graduated from Italian universities with the degree of Doctor of Medicine. Dr Natalie Colosi Wagner College professor, is general director of the Parkway Hospital.

Surgery for the training of surgeons This period of special training shall be of such character that the relation of the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry is emphasized Knowledge of these sciences as applied to clinical surgery will be required in the examination Adequate operative experience in which the candidate has assumed the whole responsibility will be required An additional period of not less than two years of study or practice in surgery (4) The candidate must present to the Board sufficient evidence of good moral character as to justify it in the belief that he will not engage in fee splitting and other dishonest practices

It is expected that the Board with the assistance and cooperation of the American Medical Association and the American College of Surgeons, will be able to increase the facilities which now exist for the adequate training of young surgeons by means of residences, fellowships, etc., of suitable hospitals

The above requirements, especially those referring to surgical training, are subject to change from time to time as the existing opportunities for training in this field of specialization may be broadened

The qualifying examination will be divided into two parts Part I, written, and Part II, clinical, bedside and practical The written part, Part I, will concern itself with general surgical problems and with the clinical application of the basic sciences of surgery to these problems This examination will cover a period of three hours each and will be held simultaneously in as many centers as are necessary to accommodate the number of applicants who are eligible Part II, is entirely oral and will also concern itself, in the main, with general surgery and, as stated for Part I clinical application of the basic sciences to the clinical problem represented In addition to this, in Part II, an examination

will be given to test the candidate's knowledge of operative surgery, X-ray plate interpretation and the principles and application of surgical anesthesia This examination will be held in as many centers as the Board may determine necessary to accommodate the eligible candidates Reexaminations will be allowed providing one year shall elapse between examinations

The fee for Group A, the Founders Group, shall be \$25 The fee for Group B shall be \$75, payable as follows \$5 for registration fee, which shall be returned if the candidate is not accepted for examination, \$20 for Part I, and \$50 for Part II The same fee will be required for each reexamination Once the candidate has become qualified, he will have no further financial obligation to the Board

This Board is a non-profit organization All fees will be used, after a reasonable amount is set aside for necessary expenses in maintaining its office, conducting examinations, etc., to aid in improving existing opportunities for the training of the surgeon

A certificate attesting to a candidate's qualifications in surgery after meeting the requirements of the Board will be issued, having been signed by its officers

Any certificate issued by the Board shall be subject to revocation by the Board at any time in case it shall determine in its sole judgment, that a candidate, who has received a certificate, either was not properly qualified to receive it or has become disqualified since its receipt

The Board shall hold its first examination (Part I, written) on September 20, 1937 All inquiries concerning applications for this examination should be received by the secretary's office promptly

Requests for booklets of information, application blanks, and other information should be addressed to the Secretary—Dr I Stewart Rodman, 225 South 15th Street, Philadelphia, Pennsylvania

INTERNATIONAL TB CONFERENCE

The Tenth Conference of the International Union against Tuberculosis, postponed from 1936, will be held in Lisbon from September 5 to 9 inclusive, under the chairmanship of Prof Lopo de Carvalho The three topics of discussion will be Radiological Aspects of the pulmonary hilum and their interpretations, Primary tuberculosis infection in the adolescent and the adult, The Open case of tuberculosis

in relation to family and domestic associates The speakers from the United States will include Dr Charles J Hatfield, Dr Henry C Sweany and Dr Robert E. Plunkett The local committee will present a program of receptions and excursions to be announced later Information regarding program, membership in the Union, etc., may be obtained from the National Tuberculosis Ass'n, 50 W 50 St, New York

The report on the cancer situation in Syracuse reveals that most Syracuse patients now travel to Buffalo to receive treatment at the state institute for cancer research. The hospitalization facilities there are limited, and Syracuse patients must make long and often painful journeys to and from Buffalo to receive treatment.

Dr Price said that many Syracuse patients should be adequately treated here, with present resources.

Ontario County

DR. JOHN A. SPENGLER of Geneva spoke on May 13 at a meeting of the Canandaigua Physicians' Club, at Brigham Hall in Canandaigua on "The Eye, the Bulletin Board of the Human Body."

Queens County

PAPERS WERE READ BY Dr I Davidsohn, blood specialist of Mt. Sinai Hospital, Chicago, and Dr William Dameshek, hematologist, of Boston before more than 200 physicians at the monthly meeting of the Williamsburg Medical Society on April 12 at the Jewish Hospital. Dr Davidsohn's paper was on "Infectious Mononucleosis, Clinic, Memetologic and Serologic," which concerns the so-called glandular fevers. Dr Dameshek's covered the diagnostic value and limitations of the sternal bone marrow biopsy, which allows for a more detailed and accurate diagnosis of obscure fevers in children.

A JOINT MEETING of the Medical Society of the County of Queens, Inc., and the Queens County Bar Association was held on April 27. The program included "Medical Jurisprudence as it Affects the Legal Profession" by The Honorable Meier Steinbrink, Justice of the Supreme Court, State of New York, "Science in Crime Detection" by Manuel E. Marten, M.D., Deputy Chief Medical Examiner for the Counties of Kings and Queens, "The Supreme Court and the President" by Max D. Steuer, Esq.

A DECREASE of eight per cent in the tuberculosis mortality rate last year has given Queens the lowest rate in the city, Dr Arthur B. Robins, superintendent of tuberculosis clinics for the Department of Health, said at a lecture in the Queens Medical Society Building on May 7.

While the average for the city as a whole was 62 tuberculosis deaths per 100,000 of population, the Queens figure was only 38,

despite an increase of $3\frac{1}{2}$ per cent in the number of reported cases, Dr Robins said.

"New subways mean new settlements, new settlements mean poorer settlements and poorer settlements mean tubercular settlements," Dr Robins asserted in discussing the extension of rapid transit in the borough.

Statistics indicate the Astoria-Long Island City district has the highest mortality from tuberculosis, he said.

THE PROGRAM of the Medical Society of the County of Queens on May 25 included papers on "Clinical Diagnosis in Gastro-Intestinal Cancer"—by John C. A. Gerster, M.D., Assistant Surgeon, Lenox Hill Hospital, Associate Surgeon, Skin and Cancer Unit of the Post Graduate Hospital, on "Malignant Bone Tumors" by Norman L. Higinbotham, M.D., Assistant Surgeon, Bellevue, Ruptured and Crippled and Memorial Hospitals, and on "Diagnosis and Treatment of Cancer of the Breast"—by William J. Hoffman, M.D., Director of Tumor Service, Queens General Hospital.

Rensselaer County

DR WILLIAM J. HOFFMAN, director of tumor service at Queens General Hospital in New York City, addressed members of the Rensselaer County Medical Society at the Health Center in Troy on May 11.

Dr Hoffman talked on "The Indications for Surgery and Indications for Irradiation in Present Day Treatment of Cancer." He illustrated his lecture with lantern slides in natural color showing characteristic cancers of different regions before and after treatment by various types of surgery, radium and X-ray.

MRS JAMES H. DONNELLY of Troy was elected president of the women's auxiliary of the Rensselaer County Medical society at an organization meeting held recently at the home of Mrs. Stephen H. Curtis at 6 Belle Avenue, Troy.

Other officers were elected as follows: Mrs. Stephen H. Curtis, president-elect, Mrs. B. T. Baker, and Mrs. John D. Carroll, vice presidents, Mrs. David W. Houston, Jr., recording secretary, Mrs. V. C. Jacobsen, corresponding secretary and Mrs. Edward M. Welles, Jr., treasurer. Meetings of the auxiliary will be held monthly.

Richmond County

SYMPTOMS WATCHED for in students under the present health education program in the high schools were described at the May

THE SOCIETY OF MEDICAL JURISPRUDENCE, at its meeting on May 10 at the New York Academy of Medicine, listened to an address on "The Value of Nonpartisan Expert Testimony" by Ramsey Spillman, M D

Niagara County

DR LEON J LEAHY, of Buffalo, was the speaker at a meeting of the Niagara County Medical Society on May 11 in the Children's building of the Niagara county sanatorium, Lockport. Dr Leahy's subject was "A Resume of Surgical Treatment of Tuberculosis." Dr Donald R McKay, of Buffalo, led a discussion following Dr Leahy's address.

Oneida County

DR GEORGE F CAHILL of New York Mills spoke on "Diseases and Injuries of the Genito-Urinary Tract" before the Utica Academy of Medicine on May 20.

THE UTICA MEDICAL CLUB met on May 13 at the home of Dr W B Roemer. A scientific paper, "Affections of the Femoral Epithysis," illustrated with X-ray pictures, was read by Dr C H Baldwin. Refreshments were served. It was announced that business meetings would be resumed in October. A club outing was enjoyed on June 3.

Onondaga County

NATIONAL RECOGNITION was given the maternal welfare campaign of the Onondaga Medical Society when it was cited by the awards committee of the social work publicity council as one of the "distinguished events of 1936-37 in the field of public health education."

Awards are made annually by the social work publicity council for outstanding pieces of social work interpretation on public health education. The maternal welfare campaign in Onondaga County was one of eight programs selected from the entire United States.

The maternal welfare campaign was instituted in September of last year and had previously been cited by the Maternity Center Association of New York, the association using the local campaign as the basis of a booklet which was distributed to 7,000 health centers throughout the United States.

THREE ADDRESSES were given at a meeting

of the Syracuse Academy of Medicine at the University Club on May 18.

Dr B C Doust spoke on "What's New About Whooping Cough," Dr E M Neptune on "Fractures of the Hip," Dr E C Reifenshtein on "Lymphosarcoma of the Gastro-Intestinal Tract." A discussion was led by Dr J Howard Ferguson.

RECOMMENDATIONS directed toward a more adequate cancer control program for Syracuse were made on May 6 before the health and hospital division of the community chest council by Dr George Price, chairman of the division's special cancer committee.

Pointing out that cancer ranks as second largest cause of death in the city and county, Dr Price said death rates from cancer have tended to increase here. In 1912 cancer claimed 57 per cent of all Syracuse deaths. In 1936 the toll was 129 per cent of the city's total deaths.

Chief among the recommendations made by the chest and council division were:

That every hospital be encouraged to maintain "tumor clinics" in conformity with American College of Surgeons' standards, or their equivalent, and that such clinics be open to ambulatory patients, not in need of hospital care.

That further study be given to the problem of obtaining needed funds for clinic equipment, compensation, radium treatments.

That the Onondaga Medical Society form a cancer clinical conference, composed of representatives of hospitals having tumor clinics, which shall serve as a co-ordinating body for the exchange of information and study of scientific phases of cancer clinical work.

That all programs of public and private health and other agencies be encouraged to include public education in all phases of cancer, and the need of early diagnosis and treatment.

That conferences take place with officials regarding more adequate compensation for treatment of dependent cancer patients.

That the health and hospital division cancer committee, enlarged to include all members of the Onondaga Medical Society cancer committee, be continued to study cancer conditions and needs in the city and county.

Dr Price said that Dr Thomas P Farmer, regional director of the American and State Cancer society, had recently recommended a countywide cancer committee and in conformity with that recommendation had appointed the medical society committee, the health and hospital division committee, plus representatives of the American cancer society, as a special county committee.

Hospital News

Should the Patient be Told?

THAT IS THE STIFF PROBLEM that rises inexorably in many hospital cases, and is undoubtedly facing scores of hospital authorities at this moment. Should the patient who is not expected to recover be coddled along with cheery predictions that everything will be all right, or is he entitled as a human being to know the facts about himself?

"It won't hurt me to know the truth I want to know I have things I must see to," said a patient at the Massachusetts General Hospital in Boston to a social worker in the tumor clinic. It is an appeal that is made constantly, and cannot be brushed aside. The social worker is Miss Isobel V Duguid, and she has been in this work for five years, and so speaks from a wealth of experience. In the *Bulletin* of the American Society for the Control of Cancer she remarks that "time and effort must be given to meet the patient's need satisfactorily." More specifically "First of all, the worker must be truthful. Truthful to herself and to the patient, but cautious, judicious and ever sensitive to the patient's mood, remembering that he or she may be sick of spirit as well as of body. She must be willing and ready to talk of death, to face death as far as it is possible, with the patient, whenever it seems wise and best at the time, not in any mysterious, morbid, gloomy way, but with a spirit of confidence leading on to the attainment of peace and finally achieving the sense of freedom in victory."

She illustrates her point with the story of this interesting case

Mrs. H. had made many visits to the hospital, with her husband, who had an inoperable cancer. He was always cheerful and appeared full of hope. Mrs. H. repeatedly said, "The doctors won't tell my husband the seriousness of his condition, will they?" I assured her they would not, unless he insisted on knowing, although we believed it might be easier for him to be told if he had asked. The time came when he was no longer able to come to the hospital. His wife came to see me. She was in great distress. She

anticipated the time when she could no longer deceive her husband. She had kept assuring him he would get well and had exhorted him to have patience, as the doctors were doing all they could for him, but it would take time. The days and weeks were passing slowly for the family. They dreaded his continual questionings and they feared how he would accept the truth.

One day I called on them. They had a comfortable and happy home and were active church members. Mr. H. was alone with his son who was carrying on his father's business. When Mr. H. and I were left alone, he turned quickly to me, saying "Miss D., you know what the doctors know. You know all about my case. Am I going to get well?" I was not surprised at the question but how to answer it was the important thing.

I said nothing for a short while, then quietly said "Mr. H. you know as well as I do." That was enough. We both knew the truth. Again the question arose. Could he accept it? He did, for his first rejoinder was, "I knew it. But why would they not tell me the truth? I want to live but I am willing to die. I dread the suffering. I hate to leave my family. Alice has been a good wife."

He hated the separation but believed it was only for a time. I tried to explain to him why the truth had been kept from him. He understood that people had meant well by trying to shield him from the facts. We talked of life and death and something of our beliefs. He was an intelligent man, he was brave and ready to face the future, whatever it held. He thanked me repeatedly for having told him the truth.

The following day I called the family on the telephone and learned that my visit had been a very satisfactory one from their point of view. They told me the tension had gone. There was a feeling of relief after the first few hours, that the truth was known to all. I called at the home a week later. It was evident a change had come.

There was a joyous note in the household, a feeling of quiet resignation and acceptance of the inevitable. Mrs. H. came outside with me and said her husband spoke freely of the future and it was such a relief not to have to lie to him all the time. I learned later that he lived only a few weeks and passed on quietly without suffering. Surely he had

meeting of the Richmond County Medical Society by Miss Dorothy R Zirbes, instructor in health education at Port Richmond High School. A symposium on fractures and X-ray work was conducted by Dr Arthur S Driscoll, assisted by Dr Lynn H Halbert, Dr Frederick M Schwerd and Dr M B Radding.

Rockland County

VERBAL BOUQUETS for the Woman's Auxiliary of the Rockland County Medical Society and suggestions as to ways in which the auxiliary may be of greater service marked the address given before that body at a luncheon and meeting held at the Blue Hills Country Club, Pearl River, on May 12, by Dr George M Richards of Stony Point, former president of the Rockland County Medical Society, and chairman of the advisory board of the auxiliary, as reported in a Nyack paper.

If the auxiliary can carry on as it has started, it will be of great assistance to the Medical Society, Dr Richards stated.

Mrs S W S Toms, president of the auxiliary, called a special luncheon meeting on June 16 at Zukor's, in New York City.

DR GEORGE A LEITNER, director of surgery at Nyack Hospital of Nyack, N Y, and at Rockland State Hospital, at Orangeburg, N Y, died at Harkness Pavilion of the Columbia Presbyterian Medical Center on May 18. He was seventy-two.

For many years, Dr Leitner was a leader of the Democratic party in Rockland County, serving as a state and county committeeman and as a delegate to the Constitutional convention at Albany in 1916. Recently, however, he had taken an active stand against the New Deal policies of the Roosevelt administration.

Dr Leitner served for many years as coroner of Rockland County and as the health officer of many municipalities. He was a director of the Nyack National Bank and Trust Company and a fellow of the American College of Surgery.

The older generation remembers him as an idol of the baseball world, in the prime of the Nyack Baseball Club of 1886, on Fordham's Rose Hill team in the 80's, on the Indianapolis National League team in 1887.

Dr Leitner pitched his first two games for Indianapolis against the New York Giants in the old Polo Grounds, winning against "Smiling Mickey" Welch by an 8 to 4 score in the first and losing the

second game, 2 to 0, to the equally famous Tim Keefe, though he allowed only four hits. His professional ball career was cut short by his father's demands that he return to finish his college term.

Schenectady County

DR DAYTON L KATHAN, 80, who practiced medicine in Schenectady for 50 years, died at his home on May 13.

To "evidence our sense of loss and grief at his departure," a resolution of respect to the memory of Dr Kathan has been approved by the Schenectady County Medical Society.

"He was an outstanding pioneer in general surgery in Schenectady for a great many years," the resolution says.

"Besides his unusual professional attainments, he combined a rare charm and personality which endeared him, not only to his patients, but to the whole profession as well."

Schoharie County

THE SEMI-ANNUAL MEETING of the Schoharie County Medical Society was held in the Central School, Middleburg, on May 11. At the scientific session the following papers were read, illustrated and discussed: "Treatment of Fractures" by Dr Frederick F McGauley, Surgeon, Ellis Hospital, Schenectady, and "Discussion of the Hernia Problem" by Dr Edwin MacDonald Stanton, Surgeon, Ellis Hospital, Schenectady.—Reported by H L Odell, Secretary.

Seneca County

THE SEMI-ANNUAL MEETING of the Seneca County Medical Society was held on May 13 at the Barnes tea room in Waterloo. Dr Arthur H Payne of Rochester gave a paper on the Bureaucratic problems in general practice. The discussion was led by Dr William Eikner of Clifton Springs Sanitarium. Twenty-five physicians attended the meeting. Dr W R Holmes of Waterloo is president, Dr E F Engel vice-president, and Dr F W Lester, secretary.

Westchester County

DR HAVEN EMERSON was the guest speaker at the meeting of the Medical Society of the County of Westchester at Grasslands Hospital on May 18. He spoke on the future of the private physician in preventative and public health practice.

completed at Utica Memorial Hospital. The first floor has an emergency unit with a minor operating and dressing room and a complete new X-ray department. On the second and third floors will be sun rooms and rooms for visitors at the north end. Eight new private rooms are located on the second floor and the third floor has five wards for six persons each.

THE TRUSTEES OF THE Brooklyn Jewish Sanitarium and Hospital for Chronic Diseases will build a six-story hospital building

in East 48th street. The project will cost \$200,000.

THE NEW ANNEX OF THE Evangelical Deaconess Hospital in Brooklyn was dedicated on April 4.

ALTERATIONS AND ENLARGEMENTS are contemplated at the Dansville General Hospital. The interior is to be remodeled and improved and an addition is to be built for use as a maternity hospital.

Newsy Notes

ANY WHO HAVE BEEN TAKING dark views of America's literary future can now cheer up. The hospitals are coming to the rescue. Some years ago a self-confessed poet named A. Tennyson Coogler wrote sadly "America's poets grow fewer and fewer, I have grave fears for her literature."

But the hospitals are going to change all that. Some of them are running poetry competitions among the patients, and we can look for burgeoning geniuses any time now. (That's the poetical word for budding.) The Sea View Hospital, on Staten Island, has just had a poetry contest, with one prize for grown-ups and another for the youngsters. One of the prize poems by the younger set was entitled "My Little Puppy," written by Miss Jennie Morelli, aged sixteen. It runs:

One time a fat little puppy was born
With a nose like a shrimp and a tail like a thorn

When given his dinner of chopped-up meat
He would step in the dish with his two front feet,

And when he finished eating it all
His tummy would feel like a cottonball

Second prize in the young people's group went to William Sawyer for his poem "The Canary." He told Miss Reynard that he "could write a lot of poems and if she waited a minute he would write another."

JEROME F. PECK, Superintendent of the Binghamton City Hospital, figures that the doctors gave nearly \$250,000 worth of free service in the hospital last year, based on the minimum rates of the Broome County Medical Society.

Using the minimum scale, he figured it this way:

327 major operations	\$49,050
706 minor operations	35,300
293 deliveries in maternity	14,650
That totals	\$99,000

But that's not all. The records also show 48,435 medical and post-operative calls. They add up to \$145,305 and the total goes to \$244,305. That's minimum. Another year it may run to \$300,000 or more.

. . .

MEADOWBROOK HOSPITAL, which operated at a loss of \$2,322 in February, showed a profit of \$1,328 in March.

. . .

FINAL ARRANGEMENTS HAVE BEEN made to develop a hospital insurance plan in Elmira. A certificate of incorporation for the "Southern Tier Hospital Service Association" will be filed at an early date. Thirty directors will be chosen to execute the plan. The board of directors will be composed of eight representatives from the Arnot-Ogden Hospital, eight from St. Joseph's Hospital, four from industry, three from the Medical Society, one from the Association of Commerce, one from the Retail Division of the Association of Commerce, one from the Central Trades and Labor Assembly, and four at large.

. . .

AN INCREASE OF almost six hundred per cent in patients using the three-cents-a-day hospital plan of the Associated Hospital Service was noted in the March report of the Greenwich Hospital. The number using the service was 68 per cent of the entire hospital patient population, as com-

gained the peace which passeth all understanding and won the victory

The worker has found from her contacts and experiences with individuals having advanced malignant disease that it is often a definite release for the patient to have someone outside the immediate family to talk with, truthfully and frankly, someone who fully understands him and realizes that he is suf-

fering mentally, in solitude, someone who feels he knows the truth, but that he has not as yet been articulate about it. Then, she is strongly convinced it is well to face the facts, to give the patient every opportunity to talk freely, even to help open the way, so that his pent up feelings may be released and so that, step by step, fearlessly, he may face the inevitable

Improvements

AN EXPANSION FUND OF \$300,000 for the enlargement of the Potts Memorial hospital, at Livingston, was voted at the annual meeting of the hospital's board of trustees on May 21. The board unanimously voted to enlarge the hospital and double its capacity. The \$300,000 will be used for additional building and equipment.

THE HANCOCK HOSPITAL at Hancock, N. Y., is to move at an early date into the nearby former Frederick Wheeler house on Wheeler street, which is to be remodeled and overhauled and equipped with maternity and operating divisions, in conformity with the new requirements of the State Department of Health. Mrs. Ethel Whitaker is to continue as manager, and the present name, Hancock Hospital, is to be retained.

DEMANDS HAVE OUTSTRIPPED the facilities of the Knickerbocker Hospital, in New York City, said President E. Moore Robinson at its seventy-fifth anniversary celebration, and "to meet this need, the board has decided not upon a campaign, but a steady, continuing effort to raise \$75,000 to erect a new two-story building and to equip it for clinic purposes. This is Urgent Need No. 1 of the hospital."

PLANS FOR "new and larger buildings" for Trinity Hospital on East New York Ave., in Brooklyn, are said to be in preparation.

THE NEW \$100,000 wing of St. Joseph Hospital on Broadway, Far Rockaway, housing the institution's pediatric and maternity wards, was dedicated June 6. The new wing, three stories in height, follows the architecture of the hospital. Provision has been made for thirty-five beds, thirteen of which are for maternity. In the basement, a cafeteria is located for the hospital's personnel.

A MOVEMENT TO BUILD a hospital for Kenmore and the Town of Tonawanda has been launched by the new Kiwanis Club there.

THE ODELL MEMORIAL SANITARIUM at Newburgh is looking over various sites to pick a new location.

THE YOUNG WOMENS HOSPITAL AID, of Ithaca, is giving to the Memorial Hospital there a \$395 delivery table, a \$400 sterilizing equipment, an emergency lighting unit, and beds, stands, screens, and drapes for the new children's ward. The money was raised by the annual Charity Ball.

BETH MOSES HOSPITAL, in Brooklyn, hopes to start a new building to supplement the present structure, which has become too small, according to President Werbelowsky.

IMPROVEMENTS to the culinary department are in prospect at the Nassau County Sanatorium at Farmingdale to cost around \$18,000.

AN ADDITION WILL BE made to the contagious building of the Meadowbrook Hospital in East Hempstead at an expense of some \$115,000.

COMMISSIONER GOLDWATER announces that his administration plans to spend \$8,000,000 in developing the Kings County Hospital, and that by 1940 it will be "one of the most complete municipal hospital units in the world, with rounded facilities for every phase of medical care and education."

IMPROVEMENTS COSTING \$35,000 including a three-story addition, have just been

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel Medical Society of the State of New York

Medical Care Under Workmen's Compensation Law

A case of considerable importance to organized medicine in this State has finally been passed upon by the Court of Appeals and the decision by that high court is one which should be of interest to all physicians who are in any way concerned with the medical aspects of the administration of the Workmen's Compensation Law.* The case was one which was originally instituted in the Supreme Court, New York County, and was there passed upon at Special Term by Mr Justice Shuentag when an application was made to test out the sufficiency of the complaint. The ruling at Special Term was summarized in the July 1, 1936 issue of the NEW YORK STATE JOURNAL OF MEDICINE. The plaintiff, defeated in the lower Court, appealed first to the Appellate Division, and thence to the Court of Appeals and the decision of that Court was handed down on May 25, 1937. Counsel for the Medical Society of the State of New York appeared as amicus curiae, and submitted briefs in each of said Courts.

The subject matter under consideration was the validity of certain of the 1935 amendments to the Workmen's Compensation Law restricting the rendering of medical care to compensation patients to physicians authorized under the Law, and providing for the participation by the various County Medical Societies in the administration of the Law.

The plaintiff in the case was a duly licensed physician, who at the request of defendant, the employer of an injured workman, had rendered medical care to the employee. The injured man was entitled to medical care under the Workmen's Compensation Law. The physician sued for the fair and reasonable value of his services. He was not, however, authorized to render medical care and receive payment therefor under the terms of the Act. The case reached the Court of Appeals by reason of a dismissal of the complaint by the Special Term upon the grounds it was insufficient upon its face.

The plaintiff in asserting the right to recover in spite of the amendments to the Workmen's Compensation Law, attacked

the validity of provisions summarized by the Court of Appeals as follows:

No person shall render medical care under the law without authorization by the state industrial commissioner, except emergency (first aid) care, or care of a patient in a hospital by a member of its constituted staff. A duly licensed physician may be authorized by the commissioner only upon the recommendation of the medical society of his county or of a medical board representing other duly licensed physicians or designated by the commissioner (section 13-b, subdivision 1). Any duly licensed physician may to that end apply to the appropriate medical society or board and in the event he fail of recommendation may appeal to the Industrial Council of the Department of Labor (Section 13-b, subdivision 2), which is empowered to recommend his authorization (see Labor Law, Cons Laws, chap 31, section 10-a subdivision 4-g). In general an injured employee may select to treat him any physician authorized by the commissioner (section 13-a 1). The employer shall be liable for the payment of the expenses of the treatment. Fees for medical services shall be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living. Recourse to the employer for payment shall be had only under the statute. Payments shall in no case be less than the amounts fixed by a schedule of minimum charges and fees to be established by the commissioner after inquiry and shall be made only to a physician or other lawfully qualified person permitted under the statute to render medical care (secs 13-a 13-f, 1). If the parties shall fail to agree as to the value of medical services, the value thereof shall be decided by an arbitration committee of physicians whose composition is defined and whose decision is made conclusive (sec. 13-g, subdiv 2). In the case of persons injured outside the state the requirements respecting selection of authorized physicians shall be inapplicable (sec. 13-b).

The Court of Appeals referred to the reasons behind the enactment of the amendments as follows:

In 1934 the governor sent to the Legislature a special message declaring the necessity for further regulation of the medical treatment and care of employees in the administration of the Workmen's Compensation Law (Cons Laws ch. 67). The subject had been investigated by a committee appointed by the governor from the memberships of accredited local medical societies. A proposed bill embodying the joint recommendations of that committee and of the

*Schild v. Outlet Embroidery Supply Co. Inc. Vol 97, New York Law Journal, p 2893

pared with 0.9 per cent in March last year. Fred J. Loase, superintendent of the hospital, predicted a rapid rise in the enrollment in the service, stating that it has been growing "by leaps and bounds" throughout the past year.

• • •

THE HORTON MEMORIAL HOSPITAL, of Middletown, has decided to give up its annual 30-day drive for funds and, instead, has engaged a professional service which will build up a list of permanent yearly contributors. Gratifying results are reported as already apparent.

• • •

THE ARTHUR B. DUEL FACIAL Palsy Clinic has been established at the Manhattan Eye, Ear and Throat Hospital in memory of the late Dr. Duel, who founded a clinic for facial palsy in the hospital in 1933 and was in charge of it until his death. Dr. Thomas G. Finkle, a former associate of Dr. Duel, is in charge of the clinic and will offer a course in the surgical technique and treatment of facial paralysis.

• • •

AT THE SUGGESTION OF Drs. S. Philip Goodhart and Benjamin Rosenbluth of the Department of Neurology, a Mental Hygiene Clinic will be opened by the N. Y. Polyclinic Medical School and Hospital, to be under direction of B. Liber, M.D., of the same department. Patients will be seen Tuesdays at 10 A.M. Its aim will be to study and treat those mentally disturbed who are still amenable to ambulatory treatment and are not in need of hospitalization.

The clinic will also pay attention to behavior problems, to faulty upbringing in children, to the exceptionally gifted and the feeble-minded. Doctors are requested to kindly cooperate.

• • •

THE GREATER NEW YORK Hospital Association was formed on May 14 at a meeting of the Hospital Conference of Greater New York and the Hospital Council of Brooklyn in the Health, Hospitals and Sanitation Building at 125 Worth Street. Approximately 100 voluntary hospitals are in the new organization.

Proposals were made at the meeting to make studies of means of obtaining increased allowances from the city for indigent patients and ambulance service. Dr. S. S. Goldwater, Commissioner of Hospitals, said after the meeting that in all probability city hospitals under his jurisdiction would also join the association. Many of them had been members of the two organizations that were merged, he said.

Willis G. Nealley, superintendent of Brooklyn Hospital, was elected president of the new group, Dr. Claude W. Munger, director of St. Luke's Hospital and president of American Hospital Association vice-president, William Seltzer, superintendent of Bronx Hospital, secretary, and George F. Holmes, superintendent of Memorial Hospital, treasurer.

The executive committee of the organization will consider the advisability of establishing a uniform schedule of working hours for nurses in voluntary hospitals, who are attempting to obtain an eight-hour day.

Events

ALUMNAE OF THE School of Nursing, the University Hospital of the Good Shepherd, returned to Syracuse from all sections of the State to join in a celebration of the fiftieth anniversary of the school's founding on May 22-24. A dance was given on Saturday evening, a religious service and a tea on Sunday, and a reunion was held at the Onondaga Hotel on Monday evening.

of Mrs. Clarence G. Bachrach. Brooklyn women will undertake the new area plan, which entails calling on every home in the borough, for the first time in the Fall when more than one thousand representatives of nineteen local hospitals and the Visiting Nurse Association of Brooklyn will take part in the campaign.

THE FIRST LUNCHEON MEETING of the new area planning committee of the women's division of the United Hospital Fund in Brooklyn was held on June 1, at the home

of THE MEMORIAL HOSPITAL Nurses Alumnae Association of Niagara Falls held its annual dinner on May 27 at the Red Coach Inn.

Across the Desk

Rocky Road of Modern Medicine in India

THE ABSURDITY OF THE CLAIM that the medical profession is "overcrowded," and that there are "too many doctors" is illustrated in reports from India. India has about 350,000,000 population and only 25,000 scientifically educated Indian physicians, yet a speaker at the last All-India Medical Conference discussed the "overcrowding" of the medical profession there. He gave the same reason that we hear alleged over and over in our own land, the tendency of young doctors to concentrate in the cities and large towns.

"If all the medical men qualifying roughly, about 1000 a year from colleges and about double that number from schools, concentrate on practicing in the large towns as more or less they are doing at present, the overcrowding and congestion in the profession, which is already existing will intensify, leading to deterioration unemployment, and misery."

The speaker was Dr. B. N. Vyas, president of the conference.

When we think of the swarming millions of India's towns and cities, harried by malaria, hookworm, cholera, and plague the idea that this handful, this wisp of physicians, are "too many," seems a bit out of line. The plain truth of the matter in India as in America, is that there are really too few doctors to care for all who are ill, but there is a lack of touch between the sick and the physician. In America there are many reasons for it, and it now looks as a result of the action of the A.M.A. at Atlantic City, as if a big effort may be made on a national scale, to bring the doctors to more bedsides where they are needed. In India, of course, deep and ancient prejudices stand in the way of Western science, and the Hakim or Vaid is called in, instead of the Indian M.D.

So the medical profession is not "overcrowded," it is the Indian mind that is overcrowded with superstitions, and overclouded with the dark shadows of primeval prejudice.

The Ancient Medical Systems

Dr. Vyas admitted that he must speak

with caution of the old Ayurvedic and Unani systems of medicine or he would himself be accused of prejudice, so he declared that he had the "highest respect" for these systems and their genuine followers. But he added rather dryly that his reverence was more or less of the same nature as that for Indian archaeology."

The old systems are suited to the temperament, spiritual feeling, and simple life of the people, but so are scores of other old customs and traditions that are melting away before the irresistible advance of Western civilization. The old-time learned urbane spiritual unselfish Vaid and Hakim are now things of the past we are told and if the old medical systems are to survive, they must be brought into modern shape. Dr. Vyas suggests that these native medicine men be required to have up-to-date scientific educational qualifications, along the line of the requirements of the basic science laws in some of our states ending with two years of clinical training.

As a matter of fact, training on these lines already exists in the Ayurvedic Faculty of Benares the Hindu University and Delhi and Lucknow Tibbia Colleges but it is "inadequate and perfunctory." What is needed is a legal standard demanding adequate knowledge and skill before the practitioner, old-style or new, is permitted to treat the sick.

Blinded by Politics

The duty of the Indian medical profession is to "convert a C3 nation into an A1 nation," declared Dr. A. Said in the address of welcome to the convention. The average expectation of life in India is only twenty-five years, against forty-seven in England, and 59.31 in America. The public are so busily engaged in political turmoil, remarked another Indian speaker, that "they are oblivious of the appalling infant mortality, lack of maternity care, continued prevalence of a large number of endemic and epidemic diseases, and the prevailing atmosphere of dirt, disease, and death."

If the people are thinking of political advancement, he added, they may well remem-

state industrial commissioner was commended to the consideration of the Legislature. The response was chapters 258 and 930 of the Laws of 1935, amending section 13 of the statute and adding thereto sections 13-a to 13-j. This case presents questions relating to the constitutional soundness of that legislation.

The mischief which the people of the state sought to eradicate was described by the governor's message in these words: "In recent years, another evil, detrimental alike to worker and employer, has developed. It relates largely to the question of medical care and treatment of the injured claimants. In many instances this treatment and care had degraded into a mere commercialized venture. Unscrupulous physicians and so-called medical clinics have operated in a way to exploit worker, employer and insurance carrier through prolonged treatment, padded bills and inferior professional service. Rebating, fee-splitting, organized solicitation of employees injured, and lifting of cases from doctors already treating them are by-products of this commercialization."

In affirming the judgment appealed from, and thereby overruling the objections to the validity of the Law as amended, the Court of Appeals in a learned opinion by Judge John T. Loughran stated in part as follows:

Plaintiff asserts that it is utterly inconsistent and, therefore, unreasonable for the state to declare a man to be a competent physician by licensing him to practice medicine and then to impose the additional requirement of a special authorization if the patient happen to be a workman victimized by accidental injuries arising out of and in the course of his employment. This amounts to saying that as among licensed doctors one must be taken to be in all cases as good a practitioner as another. We think the assertion is without support in the ordinary data of human experience, but if we are not supposed to know this to be so, then the presumption is that the Legislature inquired and found the need of special training or fitness for the treatment of compensable industrial injury and occupational disease.

An appropriate medical society or board may recommend authorization by the commissioner if it deems the applicant "duly qualified." Plaintiff objects that the judgment thus committed is unlimited with the result that due process is denied and that legislative power has been unlawfully delegated to non-governmental agencies. This criticism ignores other words of the statute which refute it. In an application for authorization, a duly licensed physician "shall state his training and qualifications" and shall agree to limit his professional activities under the law "to such medical care as his experience and training qualify him to render." He may "present to the medical society or board evidences of additional qualifications at any time subsequent to his original application." When an application is granted, "such recommendation and authorization shall specify the character of the medical care which such physician is qualified and authorized to

render" (Workmen's Compensation Law, sec. 13-b, subdiv. 2). There is here no unlawful delegation of power in violation of section 1 of article 3 of the state constitution nor is the exercise of judgment so confined obnoxious to the Fourteenth Amendment to the Federal Constitution or section 6 of article 1 of the state constitution.

The provisions designed to control the amounts to be awarded for medical services are assailed as wholly unrelated to any legitimate end of the exercise of state power. We think these are warranted as police regulations. The medical care which the employer must furnish is part of the statutory compensation of the workman. It may well have been conceived that the minimum fee requirement would effectively put a stop to unwholesome competition for opportunity to treat employees, and that it also would attract the more skillful and experienced doctors into that field. Power exists to assure full delivery of workmen's compensation to be awarded in money. Power to say that compensation in the form of medical care shall be adequate in quality is not essentially different. In the same view there was warrant for the requirement of compulsory arbitration of the value of medical services. Settlement of that fact by the varying and uneven result of ordinary litigation would perhaps in the long run impair the grade of the medical care secured to those on whose lives and safety the common welfare depends. We cannot say that there is no real and substantial relation between these limitations on the privilege to practice medicine under the law and the ends sought to be attained by the Legislature.

The exception for hospital patients and that for persons injured outside the state are denounced as arbitrary discriminations resulting in class legislation. But in one case the sufficiency of the treatment has the guaranty of quasi-official responsibility, and the other case is not fully within the control of the authorities of this state. Nor was the Legislature, acting within its proper field, bound to extend its regulation to all cases which it might properly reach.

Other objections of the plaintiff go to the validity of the amended statute under narrower commands of the constitution of the state. It is urged that voluntary medical societies are in effect made new departments of the state government in violation of sections 2 and 3 of Article V, and that compulsory arbitration of the value of medical services runs against the right of jury trial guaranteed by section 2 of Article 1. On these points it is enough to add that further discussion is foreclosed by the same fundamental law. Section 19 of Article 1 thereof provides: "Nothing contained in this constitution shall be construed to limit the power of the Legislature to enact laws for the protection of the lives, health or safety of employees, or for the payment by employers either directly or through a state or other system of insurance or otherwise, of compensation for injuries to employees, or for the adjustment, determination and settlement, with or without trial by jury, of issues which may arise under such legislation."

REVIEWED

The Control of Goiter. The Thyroid in Health and Disease By J. Thompson Stevens, M.D. Octavo of 209 pages, illustrated. New York, A. S. Barnes and Company, 1937. Cloth, \$2.50.

The author estimates that there are several million persons in the United States with thyroid disorders and with this and other thoughts in mind, he indicates in the preface that "an authoritative, yet readable book" on the thyroid should have a wide appeal.

In a book of 209 pages, the story of goiter is detailed in an easy, interesting, very readable and frequently "popular" style. In subsequent chapters, the interrelationships of the endocrines and their close association with the involuntary nervous system are freely discussed. The dominant role of the thyroid in the personality,

physique, sex, and brain is stressed. Among the many interesting and instructive chapters are those dealing with beauty and obesity, the thyroid and personality and the causes and prevalence of goiter. A chapter is given to a philosophical discussion of the thyroid and human destiny. A few careless errors have crept in but they do not seriously impair the value of the text.

Chapter XII—"Too much Iodine" is in the reviewer's opinion the high light of the book and is perhaps the most "authoritative" part. The author warns emphatically against the unqualified use of iodine in any and all forms of goiter and particularly emphasizes the dangers of self-dosing with iodine. The dangers of rendering toxic, the more or less innocuous or relatively non-toxic goiters by dosing with iodine is stressed. In commenting on the beneficial

ORDERING BOOKS

ber that "no nation weak in bodily health can ever attain political power," a statement with a world of significance in it. "If we are to live amongst the comity of nations on equal terms," he said, "we must raise our public health standard up to that of modern civilized countries." And there lies a big task for the Indian medical profession, and they are certainly not too many for it.

Quack Doctors and Quack Remedies

Signs are not lacking that the scientific medicine of the West is breaking its way through the barriers of prejudice and ancient ignorance. Gandhi himself, the great leader of opposition to everything Western, was operated on by an English surgeon when he had appendicitis. Another evidence that the people are turning to Western medicine is the appearance of a swarm of quacks. "Imitation is the sincerest form of flattery." If the people were not beginning to favor scientific medicine, quackery could not exist. The Indian quacks not only imitate the regular medical degrees, but make up new ones of their own, far more high-sounding, and exhibit diplomas more dazzling and highly colored than any medical school ever dreamed of. They are doing the "greatest possible harm," we are told, and "would never be tolerated in any other country."

And if imitation doctors are appearing on the scene, it is easy to believe that bogus medicines are coming too. Recall for a moment the terrific fight that is being waged, year in and year out, in the United States against worthless and noxious nostrums, and then imagine how the nostrum makers would deluge a vast market like India, where there is very little in the way of efficient inspection and regulation.

In fact, according to the President of the All-India Medical Conference, "no law exists to prevent the flooding of the country with spurious and dangerous preparations." Mixtures that would be poured down the sewer here by federal inspectors are shipped to India and sold over the counter to the gullible natives. Our own country is not guiltless, it appears. Our scalawags are not to be left behind by those of other lands. Said Dr Vyas:

The country is flooded with drugs and preparations of doubtful and even harmful properties. A large number of agencies of foreign countries like England, America, Germany,

France and Italy have been established throughout India. They flood the practitioner with volumes of high sounding but worthless literature. Their agents tour the country distributing free samples and beguiling the practitioners in persuasive language to use their very doubtful wares. The practitioner is led to confuse genuine products with spurious preparations and drugs, and thus acquires a tendency of empirical ways of treatment. No law exists to prevent the flooding of the country with spurious and dangerous preparations. Such a thing would not be tolerated in any other country. We must influence the public opinion against allowing this country to be made a dumping ground for useless and harmful products from all over the world. Immediate legislation prohibiting the importation of doubtful and harmful products is called for.

Poor Doctors for Poor People?

A rather interesting feature of the medical picture in India is the old idea that the poor man can get along with a poor doctor. This idea even went to the point where second and third rate doctors were turned out for service to the common people. "Why the diseases of the poor classes need a doctor with lesser qualifications passes understanding," declared Dr Vyas, and "the system of turning out medical men with a lower standard of medical education is pernicious and obsolete." It used to be said that "the Sahib needed a Doctor Babu to look after the natives," and despite all the other reforms, this old system "has been left untouched."

Proposals to raise the standards of certain medical schools are met by the plea that "there is still a demand for cheaper medical aid." To this Dr Vyas very sensibly replies that in a poor country like India it is true that the medical service to the masses "has to be necessarily cheap, but that does not imply a less qualified doctor."

Anyone who knows the proficiency of the Indian students who go to England or come to America for their education can have no doubt that they are fully able to come up to any requirements that may be established in medical education. "Our students," proudly declares Dr Vyas, "are able to acquire the highest postgraduate qualifications of the United Kingdom and other countries without the least difficulty. They can hold their own in any open competition." All that is needed, then, is to raise the standards of the poorer Indian medical

ENDOCRINES

Relation to Blood Disorders

CARL REICH, M.D., *New York City*

Adjunct Physician in Hematology, Lenox Hill Hospital, Assistant Visiting Physician, City Hospital

Blood changes in diseases of the endocrine glands have been a subject of investigation for many years. It seems a very good field for investigation because the bone marrow, the parent tissue of the erythrocytes and granular cells, is not under nervous control and must therefore be influenced exclusively by chemical and hormonal agencies. Nevertheless the findings of different schools of investigators have varied a great deal and much contradictory evidence has been accumulated. Some authors insist that in all disorders of the internal secretions there is a relative and absolute lymphocytosis, while others say that there is usually a leukopenia and an eosinophilia. There has been just as much confusion about the changes in the coagulation time in these disorders. Of course, differences in technic of doing the coagulation time may account for some of these discrepancies. Blood viscosity determinations have also been subject to very varied interpretations. The morphological study of the leukocytes has brought forward a group of investigators who feel that there is such a thing as a "lymphatic constitution" and Bauer insists that the high lymphocyte count with the reduction of the neutrophil percentage can be considered a degenerative leukocyte picture reflecting a degenerative constitutional type.

Amidst all this confusion it is difficult to find clear-cut blood changes in the various endocrine disorders and it is with some misgiving that I attempt to describe the blood findings which are thought to be associated with the more common disorders of the endocrine system. Following this I will take up the blood dyscrasias.

Addison's disease In advanced cases there is usually a secondary anemia with a lymphocytosis.

Multiglandular syndromes A marked secondary anemia is usually present in advanced cases.

Adiposity There is usually an increase in lymphocytes.

Disorders of the genital organs In animals castration results in a reduction of the hemoglobin and red blood cells with leukopenia and sometimes a relative lymphocytosis. Injection of ovarian extract in castrated females has caused a reduction of this lymphocytosis.

Increase in lymphocytes, and occasionally monocytes has been found in eunuchs.

Thymus Removal of the thymus in animals does not produce much change in the blood, aside from a lymphocytosis.

Parathyroids Removal of parathyroids will often cause an increase in the red blood count.

In attacks of tetany this is also the

effects of iodine prophylaxis in goiter districts where the endemic simple colloid goiter with its iodine deficiency predominates, he points out the necessity for accurate diagnosis and the differentiating between "prevention" and "cure." Furthermore, he warns against giving the pregnant woman iodine unless she presents real evidence of a subfunctioning thyroid gland. This chapter alone would seem to establish the merits of the book.

In the reviewer's opinion, the chapters dealing with diagnosis and treatment are the least impressive. Among other things, he cannot share the author's faith in x-ray treatment.

This inexpensive book will make good collateral reading for anyone interested in the thyroid.

ARTHUR GOETSCH

Taylor's Practice of Medicine By E. P. Poulton, M.A. Fifteenth edition. Quarto of 1136 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$8.50.

This text book of medicine appears in its fifteenth edition. It seems to hold the same relation to the medical student in England as Osler's practice of medicine in the U.S. They seem to run a parallel course, Taylor's first edition appeared in 1890, Osler's in 1892, Taylor's last edition, 1936, is number 15, Osler's, 1935, is number 12. The book is edited by E. P. Poulton assisted by five collaborators. In this respect it enjoys the advantage of greater authoritativeness and a more varied presentation that is missing in a one author volume.

The more detailed consideration of diseases of the nervous system, of the skin, and of the tropics is permitted because of the definitely smaller type used. This makes the reading more difficult, and is harder on the eyes of the student.

Infectious diseases is introduced by a discussion of the nature of infection. This is followed immediately by a chapter on pyrexia. The result of these introductory chapters has a very definite effect in stimulating an interest and arousing a curiosity to apply the information thus obtained to particular diseases.

Generally there is a tendency to summarize the morbid anatomy instead of a freer discussion of it. It surely is not presented in a manner to be of much help to the student who is beginning the study of disease.

This tendency may be excused on the basis that the pathology of diseases under discussion has already been covered elsewhere. For example the morbid anatomy of influenza is discussed in one paragraph of eleven lines. Those who have experienced pandemics and epidemics feel strongly the

inadequacy of this description. Scattered throughout the book are 71 plates, 16 of which are colored. The number of illustrations contained in the text is an agreeable departure from the average book.

Note is taken of the extensive treatment of diabetes mellitus. It is as interesting as it is instructive. The bibliography following each group of diseases is an additional feature. This work further possesses the characteristic, to a degree the peculiar property of the English textbook, in that it is easy reading.

All in all, this is an acceptable textbook of medicine and can be heartily, in fact enthusiastically, recommended.

SIMON R. BLATTEIS

The Life and Convictions of William Sydney Thayer, Physician. By Edith Gittings Reid. Octavo of 243 pages. New York, Oxford University Press, 1936. Cloth, \$2.50.

This is a biography of a famous and internationally known clinician during the early period of the development of the Johns Hopkins Medical School and Hospital.

Dr. William S. Thayer, who came from New England stock, had a most intellectual background. His father, James Bradley Thayer, was a professor of law at Harvard for many years, and his brother, Ezra, became dean of Harvard Law School. He studied at Harvard himself, was elected to Phi Beta Kappa and received his A.B. in 1885. At the Harvard Medical School, he came directly under the influence of Dr. Reginald Fitz, who interested him greatly in the study of pathology. His postgraduate work was accomplished in Berlin and Vienna, particularly under Virchow and Ehrlich.

On his return to his native land and after a short sojourn in Boston, he was invited to Johns Hopkins and received an appointment as assistant to Dr. William Osler. He maintained his connection with that institution for the rest of his life, advancing through all the grades from an assistant to a full professor of medicine.

The most interesting chapters of the biography are based on extracts from a diary kept by Dr. Thayer while he was a member of a Red Cross unit in Russia during the period of transition from the Kerensky to the Bolshevik regime and later in France as Director of General Medicine for the American Expeditionary Forces.

After the Armistice, he returned to Baltimore and took charge of the teaching facilities of the Johns Hopkins Medical School. He performed interesting work as an investigator and teacher.

The book is well written, unusually interesting and highly recommended.

WILLIAM RACHLIN

iron is absorbed best in an acid medium. In most cases iron must be kept up indefinitely. Whether or not glandular therapy can restore normal iron metabolism is still a subject for further investigation.

Pernicious anemia At present pernicious anemia is thought to be the result of a lack of specific secretion of the stomach. This secretion interacting with other elements, produces a substance which is stored in the liver and aids in the maturation of the red cells. If this intrinsic substance is insufficient the fully formed P A factor is deficient and anemia develops. The intrinsic substance is secreted by the pyloric glands and to certain extent by Brunner's glands in the duodenum. The cause of this failure to secrete intrinsic factor is unknown but many observations would suggest that there is some constitutional or endocrine factor involved.

Agranulocytosis In many cases of agranulocytosis no etiological agent can be found. It occurs most frequently in elderly women in whom there is some evidence of constitutional exhaustion. A recent study of 8000 elderly women has shown that a large number suffered from a chronic state of agranulocytosis with a leukopenia and a general feeling of fatigue. This chronic deficiency of the bone-marrow may in some way be related to a deficiency of the other endocrine organs.

Aplastic anemia Many cases of aplastic anemia occur as the result of toxic action on the bone-marrow. Salvarsan, heavy metals, and benzol are well-known etiological agents. Other cases are seen however in which no etiological agent can be found. The bone-marrow simply stops functioning. The chemical or hormonal stimulus to erythropoiesis and leukopoiesis is lacking and typical aplastic anemia develops. In most of the cases nothing can be done to help the patient. Transfusions, liver extract, iron, etc., are to no avail and death usually occurs as the result of intercurrent infection. Here again we are forced to think of constitutional and glandular causes.

Hemorrhagic diseases In discussing the hemorrhagic diseases such as hemophilia, purpura, congenital hemolytic anemia, etc., we are certainly faced with

constitutional factors. Purpura is supposed to be connected with splenic malfunction or with some anaphylactoid changes. Snake venom and splenectomy are of value in some cases. In others, in spite of these measures the bleeding continues and the platelets continue to be destroyed. Hemophilia and hemolytic jaundice are hereditary and present, on the one hand, the constitutionally different platelets, and on the other the spherical microcytes. Endocrine factors must play important roles in these hereditary and constitutional conditions.

Polycythemia and Leukemia I wish to speak of these two conditions together because they have many points in common and cases of polycythemia have occasionally ended up as leukemia. Much literature has come to the fore which considers these conditions as the result of a disturbance of correlation of the glandular mechanism. While I do not agree with this concept, but rather lean to the neoplastic theory of leukemia, I think that it is of interest to present the arguments of those in favor of this theory.

Ziegler and his followers have insisted that the leukemias should be considered as disturbances of the hormonal regulation of leukopoiesis. Their arguments are as follows. In the embryo there is first an enormous development of myeloid cells. In the latter period of embryonic life, the lymphatic system begins to develop and the myeloid cells commence to recede. After birth and in the young child, the lymphatic system dominates, as shown by the lymphocytosis in the peripheral blood and the greater frequency of lymphatic leukemia in children. As puberty approaches, with its changes in the organs of internal secretion, the thymus and other lymphatic tissues go into a stage of involution and the lymphocytosis diminishes.

The bone-marrow which is apparently not regulated by nerve fibers, must therefore be regulated by chemical or hormonal influences which at one time call forth a myeloid development and later a lymphatic development. It is therefore easy to see that a disturbance in the internal secretory regulation could produce an overproduction of lymphatic or myeloid tissue, with resulting leukemia.

In discussing the leukemias from a

cause in connection with a marked increase in the total and relative lymphocytes

Acromegaly There is usually an increase in the lymphocytes

Hyperthyroid The hemoglobin and red count are usually normal. The total leukocytes are normal or diminished with a relative increase in the lymphocytes. The eosinophils are usually increased. In severe cases there is not only a relative but also an absolute lymphocytosis. This not only reflects a hyper function of the lymphatic apparatus but indicates that there is a slight maturation arrest of the polys in the bone-marrow. After successful operations, the blood picture frequently returns to normal. Colloid goiter usually shows a normal blood picture.

Feeding of iodides or thyroid extract will produce a rise in the number of lymphocytes

The coagulation time is usually somewhat prolonged, but this is a subject of some dispute. Experimentally, guinea pigs fed thyroid and iodides showed an increase in the lymphocytes, a prolongation of the coagulation time, and a maturation arrest of the granular cells in the bone-marrow.

Hypothyroid In myxedema, as a result of the reduction in the metabolism, there is also a reduction in the bone-marrow metabolism, with a subsequent fall in the hemoglobin and red cells. The color index is usually over one and there is very little evidence of active blood regeneration.

Experimentally it has been found that removal of the thyroid gland is followed by poor blood regeneration. There is usually not much change in the white blood cells in hypothyroid conditions.

Pancreas The only disease affecting the blood which seems to be connected with the pancreas is hemochromatosis. Here the body seems to have lost the ability to use iron in spite of the enormous quantities of iron in the organs, hence, anemia is frequently present.

I will now briefly mention the effect of the injections of gland extracts on the blood cells.

Insulin Temporary fall in platelets

Thyroid extract A temporary rise of platelets and the appearance of young polys

Adrenalin There is usually first an increase of the lymphocytes, then of the polys. This is not constant.

At this point I wish to make some brief mention of the spleen as an organ of internal secretion. There seems to be some hormonal relation between the spleen and the bone-marrow. Removal of the spleen causes an increase in the number of young red cells in the peripheral blood and hyperplasia of the bone-marrow cells. This may mean that the spleen secretes some hormone which depresses bone-marrow function.

I now come to some of the blood dyscrasias and will attempt to show that there is some endocrine factor in most of them.

Idiopathic hypochromic anemia This disease, formerly called chlorosis is seen almost exclusively in women. In many cases it is connected with nutritional disturbances and frequent pregnancies, but in others these factors do not seem to be present and we must look for some other disturbing influence. In the earlier descriptions of chlorotic girls, frequent attention was called to the pigmentation of the skin. This is reminiscent of disturbances of adrenal function.

Many of these chlorotic girls also had colloid goiters and an abnormal increase of the fatty tissue. The sex organs were frequently hypoplastic, indicating maldevelopment of the ovaries. We can therefore say that in some cases of hypochromic anemia there is probably a functional insufficiency of the ovaries. The ovary has a marked influence on the other glands of internal secretion and a hormonal disturbance of this type could theoretically disturb bone-marrow function with its subsequent poor erythropoiesis. The anemia in these cases is usually secondary in type with a low color index and a leukopenia. Many cases have been recently described in older women. The picture is often complicated by glossitis, dysphagia, and a lack of free hydrochloric acid in the gastric contents. The treatment is very simple. Large doses of iron produce a prompt rise in the reticulocyte count and within a few weeks the anemia is markedly improved. It is important in those cases with a true achylia gastrica to administer hydrochloric acid as it has been found that

SUPRACLAVICULAR BRACHIAL PLEXUS BLOCK

An Accessory Therapeutic Measure in Arthritis of the Shoulder Joint and Allied Conditions

JAMES M. TARSY, M.D., *Brooklyn* and OTTO STEINBROCKER, M.D.,
New York City

From the Arthritis Clinic, Fourth Medical Division, Bellevue Hospital, New York City

Introduction

The frequently delayed response of arthritis and related conditions, particularly in the shoulder-joint, to constitutional and specific therapy, led us to seek some means of immediate relief of the local joint symptoms until general measures prove effective. The accepted use of the supraclavicular brachial plexus block by procaine in regional anesthesia, and its simple technic, suggested its possible value in the painful shoulder conditions presented at our clinic.

A series of twenty-one patients with pathology of the shoulder region, therefore, was selected in order of appearance for this method of treatment. They were ambulatory cases, with subacute or chronic disease, who gave a control history of failure to improve by the usual medical and physiotherapeutic measures prescribed in our clinic and elsewhere during a reasonable period. Extremely debilitated or senile individuals, severe cardiacs, uncontrolled diabetics, and those known to show procaine sensitivity, were excluded.

Anatomical Considerations

The brachial plexus¹ located in the posterior triangle of the neck, emerges between the scalenus anticus and medius muscles. It pursues a downward and outward course close to, and just external to, the subclavian artery. In the supraclavicular fossa, it lies rather superficially, one-three cm. in depth, depending on the amount of superficial adipose tissue, and is therefore readily accessible. The landmarks are also quite definite, the plexus occupying a closely limited area.

As it emerges between the two muscles mentioned above, and runs downward and

outward in its course under the first rib and clavicle, the plexus lies just external to the subclavian artery. At the point of blocking, it is bounded anteriorly by the clavicle, medially by the subclavian artery, and posteriorly by the first rib. The loose areolar tissue by which it is surrounded permits the injection of a considerable quantity of fluid without ill effects.

Technic

The most practical route for injection is the supraclavicular,² because at this area the brachial plexus has not yet divided, and anesthesia of all its branches may be effected. Of the methods of approach, we are describing the one we have found most desirable.

The patient sits erect on a high stool facing the operator. The chin is turned to the side opposite that being injected. The subclavian artery is now located in the supraclavicular fossa by placing the middle or index finger just over the upper surface of the clavicle at its exact midpoint, as a rule. A pulsation indicates the location of the artery as it courses downward making an angle with the clavicle. The point of pulsation is marked with an iodine soaked applicator by a vertical line extending below the clavicle and over the upper part of the thorax. This line acts as a guide in avoiding the subclavian artery. Difficulty is sometimes experienced in palpating the pulsation of the subclavian. This anomaly should cause no concern, since it indicates that the artery is protected by the clavicle and less exposed to puncture.

The exact point of injection is the angle formed by the clavicle with the subclavian artery, and slightly external to the point of pulsation. This site corresponds usually to the midpoint of the

neoplastic standpoint we have even more interesting findings. Recently Cook and Kennaway found that dibenzanthracene and methylchloranthrene will produce neoplasms when injected into animals. These chemicals are related to certain products in the body—particularly those found in the bile and in the female sex hormones. The chemical formulas of theelin and the carcinogenic agents mentioned show points of similarity. Therefore in the near future we may find that

the leukemias may be created by disturbances in the function of the endocrine organs. This disturbance would not be one of correlation as postulated by Ziegler but one of actual endocrine metabolism with the production of faulty endocrine metabolites. These substances could then irritate the bone-marrow cells, disturb their internal regulating mechanism, and initiate an uncontrolled proliferation with a resulting leukemia.

41 W 82 St

HOT WEATHER HAZARDS

Now is the season when thousands of people will expose their skins to the sun, to gain the abundant health and vigor popularly associated with a coat of tan. Others seek the same result under ultraviolet lamps. The evidence, however, says Allen S. Johnson in *Hygeia*, that either sunlight or artificial ultraviolet light will cure the vast array of skin or systematic disorders treated by it is of the most scanty and equivocal character. Nor is it certain that sunlight is absolutely essential to health. The Eskimos of northern Greenland seem to get along quite well without any appreciable exposure to ultraviolet light, and mules employed in coal mines do not appear to suffer any ill effects as a result of being deprived of sunlight altogether. As far as normal persons are concerned, the claims that exposure to ultraviolet rays increases or improves the tone of the tissues or of the body as a whole, stimulates metabolism or tends to prevent colds have not been conclusively proved. On the other hand, great harm may be done to patients with pulmonary tuberculosis and various skin diseases by unwise exposure to sunlight. Even normal and apparently healthy persons may be made seriously ill by immoderate exposure to intense sunlight without a period of preliminary adaptation. If a sufficiently large area of the body is sunburned, as may happen when it is protected only by a bathing suit, the victim will react much as if he had suffered an ordinary burn from exposure to fire. Malaise, prostration, a high fever, and evidence of kidney derangement are not uncommon. Yet each summer sees a host of self-elected martyrs who voluntarily attempt to burn themselves to a crisp in the shortest time possible.

Because a tan is usually acquired in healthful surroundings it is erroneously assumed that the mere tan per se represents

the *modus operandi* of these healthful influences. Large areas of pale untoughened skin are suddenly exposed to an intense summer sun, which is often intensified by reflection from an expanse of water or cloudless sky. An hour passes without significant change. There is no tan and scarcely any sunburn. Yet already the skin has received sufficient radiation to cause severe and painful sunburn six hours hence. Unfortunately this is not realized, and the wretched sun worshiper settles down in real earnest to acquiring that tan which is regarded as proof of a healthful happy vacation.

Then follows an agonizing night of parched burning skin that puffs into gossamer thin blisters, which in turn break and spill their sticky contents over everything within reach. No wonder two weeks is the conventional vacation period for it is usually just about adequate for the sun worshiper to recover sufficiently to return to civilization conventionally clad.

We pride ourselves in this country on our humanitarian institutions dedicated to the alleviation of suffering, yet the same chumps get sunburned year after year. A few simple measures would save a vast amount of discomfort and some serious illness without detracting from the tan which is sought. In the first place some persons are unable to mobilize the skin pigment which constitutes tan and protects the skin from sunburn. They must learn that their only hope of salvation is to keep their shirts on. Blonds and redheads tan slowly and must be exposed for only short periods at first until their skins become accustomed to intense sunlight. Their undoing is usually a desire to get tanned in a few days so that they can give the impression they have been there all summer.

with rheumatoid arthritis, every one of the seven patients benefited from the therapy. Of the seven patients with osteoarthritis, six showed a varying degree of definite improvement. One patient with subdeltoid bursitis showed complete recovery from symptoms and disability after receiving ten injections, while two patients with subacromial bursitis, each of whom received two injections without improvement, failed to return after two weeks of observation. In refractory subacromial bursitis, when our simpler procedure fails, we propose to inject the bursa directly according to the technic of Haggart and Allen.⁴ Two patients with brachial neuralgia and subacromial bursitis combined, showed excellent recovery after long disability preceding treatment. One patient with brachial neuralgia was entirely relieved, whereas another patient with a similar condition received slight or no benefit.

In the neuralgia group, then three of the patients presenting brachial neuralgia alone or associated with bursi-

tis, made excellent recoveries, while one failed to show satisfactory response to treatment. Stubborn cases of the latter type are worthy of a trial with x-ray therapy as employed by Zimmerer and Cottentot⁵ who report a high percentage of response in a variety of neuralgias treated by radiation.

About a year after this series had been treated, the patients were sent cards inquiring after their condition and inviting them to return to our clinic for check-up. Four patients responded. One with rheumatoid arthritis answered that the injected shoulder had been comfortable, one patient with bursitis answered similarly. One patient with osteoarthritis came to request medication for occasional pain in the shoulder. Severe limitation of mobility, which had disappeared under injection, had not recurred and the former localized tenderness was almost entirely absent. Another patient with osteoarthritis had experienced practically complete relief of pain and disability for nine months. About three months before receiving our notice the pain had recurred accompanied by a slight limitation of motion which the patient had not noticed. This group of four patients represents only a small part of the series we are reporting, but does, we believe, serve as an index to the results to be expected, at least in some of these patients, and as an encouragement for more extensive trial of plexus block in the conditions enumerated.

clavicle A wheal is raised at this point with one per cent procaine solution while drawing the skin down over the clavicle A needle about five cm long and 22 to 23 mm gauge is inserted through the wheal The needle is then best directed at right angles to the skin for half to one inch, when it will strike the first rib Having hit the rib, the needle is gently moved upward and medially to elicit paresthesia which indicates location of the plexus Slight resistance is offered by the cervical fascia, but as soon as this tissue is passed, the needle-point lies in the space containing the brachial plexus

When the brachial plexus is engaged, the patient experiences a quick, sharp pain running down the arm, possibly down the forearm to the finger tips as well, and is instructed in advance to expect and to announce this sensation If paresthesia is not elicited, the needle is aimed toward the tip of the transverse process of the sixth cervical vertebra When the patient feels the typical, lancinating pain down the extremity, aspiration failing to reveal blood, five-ten cc of one per cent procaine are slowly injected Aspiration should be done several times in the course of the injection

When the injection is successful, the patient complains shortly of heaviness of the arm Within ten-fifteen minutes anesthesia occurs The arm becomes paretic Pin-prick elicits no pain, only a sensation of pressure The skin becomes flushed and warm in marked contrast to the opposite extremity Little benefit is to be expected unless paresthesia is achieved Any stretching or indicated passive manipulation is performed, and the extremity is now carried in a sling The dangers of the procedure are obviously puncture of the subclavian artery and of the apical pleura and lung Puncture of the artery occurred twice early in our series without any untoward effect The needle was immediately withdrawn with the first gush of blood into the syringe and, after a brief rest, the block was repeated in routine fashion without any adverse symptoms We have had no pleural or pulmonary mishaps

Method of Treatment

In this series, we treated all pain-

ful, disabled shoulders in patients not presenting contraindications already mentioned There were, as enumerated in Table I, seven patients with rheumatoid arthritis, seven with osteoarthritis, two patients with subacromial bursitis, one with subdeltoid bursitis, two with brachial neuritis and subdeltoid bursitis, two with brachial neuritis The diagnoses were established by accepted clinical signs and symptoms, and x-ray studies

Although the sites of pathological change varied in this heterogeneous group, we felt that the therapy would be directed at a common seat of relief, the brachial plexus As Table II indicates, all of these patients presented a moderate to complete loss of mobility of the involved joint and extremity, accompanied by pain of varying degree in almost every case The symptoms had existed for a period of two months to ten years Acute conditions, and those already showing improvement under other therapy, were not treated in this series No cases were included unless objective evidence of disability accompanied the symptoms In addition to pain, the objective features usually were limited mobility, atrophy, swelling, localized tenderness on pressure

Injections were administered once a week and averaged four per patient in this series Five-ten cc of one per cent novocain was the usual dose Simple manipulation was employed following injection when indicated Patients also were given exercises to perform at home

We believe direct single brachial plexus block offers a more desirable approach in the relief of shoulder pain than the multiple, periarticular method described by De Seze³ In rheumatoid disease particularly, the direct injection avoids repeated penetration of the affected periarticular tissues

Results

Improvement was considered moderate when pain ceased and a fifty to seventy-five per cent recovery of function occurred An excellent result was indicated by functional recovery of seventy-one hundred per cent Seventeen patients in the series, showed moderate to excellent improvement In the group

PROTAMINE ZINC INSULIN

Hypoglycemic Reaction

EDWARD TOLSTOI, M D, *New York City*

*From the New York Hospital and the Department of Medicine,
Cornell University Medical College*

On February 1, 1937, there appeared an announcement for the medical profession that protamine zinc insulin was commercially available. This announcement will, no doubt, be received with great enthusiasm as the physician and diabetic patient have been hearing a good deal of this new preparation from the medical and lay press. And, since some publications have declared that the discovery of protamine zinc insulin signifies a distinct advance in the treatment of diabetes mellitus a wide use of the new preparation is to be expected. It is because of this anticipated situation, that this communication is warranted. It proposes to deal with the hypoglycemic reactions associated with the application of the new preparation particularly, since the descriptive literature circulated by the manufacturers reads "Hypoglycemic reactions following the use of protamine zinc insulin are not so frequent as those following the use of unmodified insulin." Another booklet states that "although the use of protamine zinc insulin has reduced the occurrence of symptoms of insulin reactions," such reactions may still occur and furthermore that the hypoglycemic symptoms may be of longer duration.

From personal experience with this product it is my feeling that the hypoglycemic reaction induced by an overdose of the new preparation is a drawback in its general application in the ambulatory case. It is my impression that insulin shock has not been reduced but on the contrary, increased both in frequency and severity with the use of the protamine zinc preparation. True it is, that we have used the new preparation for a short period of three months and have not yet learned its pharmacologic action. This may, of course, explain the greater frequency of our hypoglycemic reactions. As a matter of fact we have observed more severe insulin reactions in the past three months, with the protamine zinc insulin than during the preceding year with the

unmodified insulin. This may have been due to the difference in premonitory symptoms and the duration of the hypoglycemia once established. With the regular insulin the reaction is mild and rapidly controlled. The patient in most instances can relieve himself of the symptoms by means of orange juice or some solid sweets. He may then tell the physician that as soon as he felt nervous and began to perspire he ate a lump of sugar and his symptoms promptly vanished. The hypoglycemic state as induced by the new preparation is severe and it may strike with great suddenness. The patient often had no warning and some patients stated that "it sneaked up upon them." There were hardly any prodromes and sweats were not always present.

Hypoglycemic reaction developed in five out of a total of fifteen patients receiving protamine zinc insulin. All of the patients, except one, were ambulatory either outpatients or office cases. Three of the patients developed stupor. In the patients who did not become stuporous, there appeared premonitory symptoms such as tingling of the extremities, twitching of the mouth, headache, slight dizziness, and some psychic manifestations. In one of these "mild" hypoglycemic reactions the symptoms persisted for nearly three hours in spite of the repeated doses of orange juice, sugar, and milk.

In the following illustrative cases only the facts pertinent to the hypoglycemic symptoms resulting from the use of the protamine zinc insulin are emphasized. Details usually given, whenever the treatment of diabetes mellitus is discussed, are purposely omitted as having no bearing on the topic under consideration.

CASE 1. A sixty-seven year old man, had had diabetes for fourteen years. He managed to carry on, on a diet of protein seventy grams, fat seventy grams, and carbohydrate 200 grams, with twenty-five

Discussion

In this study, brachial plexus anesthesia gave moderate to excellent improvement in seventeen of twenty-one patients with severe disability and pain in the shoulder. Because of the diversity of conditions in which the results are elicited, it is interesting to consider the mechanism of pain and its relation to these diseases. Like others, we have observed that in many of these patients a great part of the disability is due to prolonged reflex muscular spasm with ensuing atrophy of disuse and deformity. Relief of pain, even for a short period, in many of these cases, not only restores function but also gives the patient a freedom from the fear of pain which is undoubtedly a great factor in chronic joint disability.

The question arises how a temporary anesthetic such as procaine can bring about recovery in long-standing disease of this kind. It is perhaps difficult at first thought to accept the idea that such treatment can produce recovery in any long-standing disability. A psychic element is, therefore, suspected and cannot be ignored in the disability of these conditions as in all long-standing disease.

It must be remembered, however, as has already been pointed out, that in nerve block procedure the interruption of prolonged pain appears to have more lasting effect in the suppression of the sensory cycle than the mere duration of the anesthesia itself. The threshold of pain is thought to be elevated by such interruption of the persistent pain cycle and its reflex disturbances. As a result, the sensitiveness of the patient to the usual pain stimulus is diminished. At the same time with the temporary abolition or diminution of the sensory reflex mechanism, the tense muscles are relaxed, the joints, accordingly, are permitted greater mobility, the patient gets rest and relaxation not allowed for a long period in these chronic conditions. Such relief, if sufficiently repeated or prolonged, evidently suffices to restore normal joint function in many cases.

The plexus block exercises no specific action, of course, in the conditions with which we deal here. It is primarily an accessory measure for the local relief and control of long-standing discom-

fort. Patients suffering from chronic arthritis and allied conditions are tired and worn by their stubborn symptoms. To afford them rest by relief of pain and spasm is to furnish a basic requirement for increased resistance and recovery. The procedure so far, has demonstrated promising effectiveness for these purposes and we hope this report will encourage more extensive trial of plexus block and other forms of local analgesia for the relief of arthritis and related conditions.

Conclusions

Supraclavicular brachial plexus block with one per cent procaine in chronic arthritis and allied diseases of the shoulder is a useful accessory therapeutic measure. This method appears to be particularly valuable in those refractory cases accompanied by considerable pain and limitation of function in which the customary systemic and local measures have proved ineffective. The procedure is valuable also in those shoulder conditions in which disability is accompanied by soft tissue changes and the formation of adhesions. By its antispasmodic effect and anesthesia, the method lends itself to moderate manipulation and breaking-up of adhesions. In trained hands, brachial block should be devoid of danger.

Summary

1 Supraclavicular brachial plexus block with one per cent procaine in a group of twenty-one ambulatory patients with chronic arthritis, bursitis or brachial neuralgia proved effective in seventeen of the patients, unsatisfactory in four.

2 It is a simple procedure affording relief of pain, relaxation of muscle spasm, and improvement of disability.

3 It is a promising accessory measure in the treatment of chronic arthritis and allied conditions of the shoulder joint.

thirteen years received thirty units of protamine zinc insulin at 11 A M. He had been receiving this dosage for about two weeks. He ate a small lunch, but a liberal dinner as his prescribed diet was about protein seventy grams, fat sixty grams, carbohydrate 250 grams. At 11 30 P M his friends noticed that he became quite playful, very talkative and acted foolishly. He removed his coat and began playing with it. He realized that something was amiss, but could not control himself. He finally left his friends to go home, but stopped on the way for orange juice. He drank two glasses of orange juice, one of grape juice, and ate two pieces of toast. He reached home at about 1 A M. Even then he was shaky, incoherent, and had slight twitching about the mouth. His sister gave him two glasses of milk and he felt better at about 2 30 A M. The reaction set in about twelve hours after the administration of the modified insulin and lasted about three hours in spite of treatment.

CASE 5 A young woman in the twenties who has had diabetes for about four years needed four doses of insulin to keep her regulated. The regulation, however, was always difficult. Two doses of insulin were substituted for the four. She was given twenty-five units of the unmodified insulin and forty of protamine zinc insulin before breakfast and dinner respectively. Before a holiday she danced a good deal and on the following morning she was found in the kitchen, playing with empty bottles and acting foolishly. Her actions were purposeless. She was accused of being drunk and was forced to go to bed. During the arguments and the struggle in getting her to bed she recovered sufficiently to suggest an insulin reaction. The treatment was then begun and she was again herself in about two hours. The reaction set in about sixteen hours after the protamine zinc insulin and lasted over two hours.

From the presentation of the data it is obvious that the hypoglycemia resulting from the use of protamine zinc insulin may appear from ten to twenty-four hours after its administration. Furthermore, it is also apparent that the duration of the reaction may be prolonged unless treated by adrenalin or intravenous medication. With the unmodified insulin, the maximum effect was anticipated in four to six hours, and if a reaction was imminent the patient had ample warning because of the tremor, nervousness, and sweats. With the onset

of these manifestations he drank some orange juice or ate a piece of sugar and in most cases recovered sufficiently to carry on until the following meal. There were some patients in whom the various stages of the insulin reaction followed each other very rapidly with resulting unconsciousness, fortunately such cases were infrequent. With the modified insulin, although it is believed that the maximum effect is reached approximately from twelve to twenty-four hours, this approximation is not at all predictable. The reaction may occur sooner, or at any time during this interval. It may strike suddenly, and in some cases totally without warning. It is stated that the patients may have feelings of uneasiness or vague discomforts, but close questioning of our patients who experienced the *severe* reactions failed to elicit any prodromal symptoms. This is an undesirable and disturbing feature, as neither the patient nor the physician can be certain when a reaction will occur—a situation not at all conducive to mental relaxation and comfort. This feeling of uncertainty is easily understood, as under practically similar circumstances, diet, and management, the patient will manifest reactions on certain days and be free from symptoms at other times. Whether this is due to the cumulative effect of the protamine zinc insulin or to the patient's improvement in tolerance is a point which more extensive clinical trial will determine. Exercise may be a contributing factor to hypoglycemic reactions as it was noted in two of our cases. However, in others it was not a contributory cause. Whatever the ultimate explanation, the fact remains that because of our unfamiliarity with the preparation, and because of our inability as yet to predict certain phenomena when using protamine zinc insulin it is imperative that we exercise the greatest caution in its application. Since the ambulatory patient cannot be observed as continuously as the hospital case it is of utmost importance to inform patients, that the development of any unusual feeling no matter how vague or trivial, demands immediate ingestion of some form of carbohydrate. The treatment furthermore should not stop there, but the patient should then take some carbohydrate containing food

units of insulin in the morning and fifteen units in the evening. The insulin was given twenty to thirty minutes before meals. On this regime he was sugar-free most of the time. He entered the hospital because of a loss of weight, in spite of the fact that he continued to increase the daily amount of insulin. A hyperchromic macrocytic anemia was found and the patient was being studied. During his hospital stay it was decided to substitute one dose of protamine zinc insulin for the two injections of the unmodified preparation.

His diet was increased to protein eighty grams, fat ninety grams, and carbohydrate 250 grams. He was also given forty-five units of protamine zinc insulin one hour before breakfast. He had remained on this regime for five days when one morning early he was found in bed, pale and cold. His eyes were fixed and he mumbled some unintelligible sounds. *He was dry and not perspiring.* The blood pressure was 130 systolic and 80 diastolic. There were no convulsions. The intern, Dr. Timpanelli, administered fifty c.c. of a fifty per cent glucose solution intravenously and the patient promptly responded. Following this hypoglycemic reaction, the protamine insulin was reduced to thirty-five units daily. However, after two days on the reduced amount he again was found in bed, stiff and comatose. He was salivating and evidently had been unconscious for some time as there was a good deal of saliva on the pillow. Again glucose was given intravenously with recovery. The patient had insulin for fourteen years and he was well familiar with the premonitory signs of insulin shock. He stated that he had no warning whatever before becoming ill. The reaction in this patient occurred about twenty-four hours after the administration of the protamine zinc insulin.

CASE 2 A fifty-nine year old female was treated for diabetes in the clinic for nearly five years. Before substituting the unmodified insulin she managed to get along on a diet of protein seventy grams, fat sixty grams, and carbohydrate 150 grams. Her insulin requirements were twenty units in the morning, five at noon, and fifteen before the evening meal, administered at the customary twenty to thirty minutes before meals. At first, ten units of unmodified and twenty-five of the protamine zinc were tried. These were given into different sites about thirty minutes before breakfast. After a short period protamine zinc insulin only was used. The diet was unchanged. For the past week she had received thirty-five units of the new prepa-

ration. She administered her insulin in the morning and then after placing some edibles on the fire she decided to rest for a while. She recalls nothing except that she awoke in the hospital. Her sister had found her unconscious, cold, drooling at the mouth, and glassy-eyed. A physician was called and he advised immediate hospitalization. She was brought to the hospital at 11 A.M. about three hours after the administration of the insulin. Her blood sugar was twenty-seven mg per 100 c.c. Dr. Meakins administered twenty-five grams of glucose intravenously, and the patient promptly regained consciousness. She was then given 200 c.c. portions of orange juice every two hours until 8:30 P.M. It is more likely that the reaction occurred about twenty-four hours after the protamine zinc insulin. The insulin taken on the morning of the reaction may have been a contributing factor. The probability is, however, that the previous day's insulin was chiefly responsible, as it is well-established that the action of protamine zinc insulin lasts for twenty-four hours and even longer.

CASE 3 A young woman of twenty-four years had had diabetes for about three years, which was controlled without any difficulty on a diet of protein sixty grams, fat sixty grams, carbohydrate 300 grams. To maintain a sugar-free urine the insulin requirement was fifteen units before the morning and ten before the evening meals. Following a severe *Streptococcus hemolyticus* pneumonia with empyema from which she made an uneventful recovery, it was necessary to increase her insulin to forty units daily in two doses—twenty-five and fifteen. One dose of thirty-five units of protamine zinc insulin was then substituted. This was given before breakfast, and she had remained on this dosage for about two weeks. On the day before the new year she took the protamine zinc insulin at the usual time, had her meals as she has been having them for the past two weeks, but in the evening joined a party of friends to usher in the New Year. The following morning she was found in bed unconscious, cold, her eyes fixed. The physician who saw her administered one c.c. of 1:1000 adrenalin hypodermically and as she failed to respond after twenty minutes an additional 0.5 c.c. was given. Following this she was sufficiently revived to continue further treatment by mouth. There is no certainty as to whether or not she was perspiring. The reaction occurred here about twenty-four hours after the modified insulin was used.

CASE 4 A young man of twenty-three years who has had diabetes for the past

BUERGI'S THEORY

Applied to the Treatment of Secondary Anemia

HENRY ALMOUR, M D, *New York City*

Buergi,^{1,2} in 1932, demonstrated that two different substances causing identical therapeutic manifestations when combined were increased in their effects if they possessed identical pharmacological points of attack. He and his followers concluded that small doses of certain substances will produce a better effect if combined than will larger doses of the individual substances. It is known, that when prescribing the coal-tar products in influenza, the combination of several will yield better results than when only one is used. Here, we have an *increased* effect because of the *similar* pharmacological points of attack. If, however, one adds to these drugs codeine and caffeine the results obtained will be far greater. This can be explained as the effect being *multipled* because of the *different* pharmacological points of attack. Since this holds true in the treatment of "grippe," it should also hold true in the treatment of other pathological conditions.

The author has selected a series of cases of secondary anemia, and has treated them with a combination of the hematopoietic drugs. Be it understood that the so-called shot-gun prescription is not advocated since it treats a number of symptoms which are manifested in one disease, whereas each and all the hematopoietic drugs attack only one symptom, *i.e.* secondary anemia.

At this time it would be advisable to review briefly the pharmacological action of the various drugs for the treatment of anemia at our disposal. The basis for the use of iron medication lies in the ability to stimulate the hematopoietic system.⁴ After leaving the liver, where iron is stored, it is received by the marrow cells whose nuclear chromatin liberates it to the hemoglobin. Iron thus becomes a "building stone for hemoglobin."⁵ Clinically pure iron, according to Schultz, aids at first, but with massive therapy, symptoms of lassitude, headache, and salivation result. He explains these phenomena as

a result of the congestive effect produced, and he is of the opinion that the anemic individual requires but little iron to obtain favorable results. Iron can be assimilated and stored in the liver, but as such it cannot be used for the production of hemoglobin. It is, therefore, of primary importance to bring about utilization of this stored iron. For this purpose Waddell⁶ found copper to be most efficacious. Compared to its ability to supplement iron in the production of hemoglobin, the heavy metals did not approach copper. Supplemental proof of this fact was furnished by Elvehjem.⁷ A diminution in the hemoglobin of day-old chicks was accomplished by dietary restrictions, and iron free of copper was fed them in an attempt to bring the hemoglobin back to normal. This met with failure. However, when small amounts of copper were added, the hemoglobin rapidly approached the normal limits. It must be remembered that copper does not function in the assimilation of iron, but acts in the conversion of iron into forms which can be utilized in the construction of the hemoglobin molecule. The administration of various forms of copper in anemias following hemorrhage led Handovsky⁸ to believe that this metal served to stimulate erythrocytic activity.

Besides serving as a mobilizer of iron and as a red cell stimulant, Hesse^{9,11} found that copper acts as a detoxifying agent to thyroxin. He observed that 4 mg of copper per kilogram of body weight compensated thyroxin poisoning in dogs. He believed that copper was of value in combating the poisonous effects exerted by thyroxin, such as, exhaustion of fat centers, hypertrophy of heart and liver, disappearance of glycogen from the liver, etc. Further, he is of the opinion that copper and iron will also aid in the treatment of Graves' disease, the action being due to the formation of insoluble, nontoxic copper thyroxin compounds.

The largest part of assimilated copper

which will be more slowly absorbed thus supplying the body with glucose in case the reaction tends to be prolonged Bread and milk are suitable for this purpose

Conclusions

1 The use of protamine zinc insulin may be associated with sudden, severe prolonged hypoglycemic reactions These may set in without any prodromes and sweats need not necessarily be present

2 The time of onset is not predictable as reactions may occur as soon as ten to twelve hours, and as late as twenty-four hours after the use of the modified insulin

3 This unpredictability of maximum effect creates a feeling of insecurity on the part of the patient and a state of apprehension on the part of the physician

4 Until more facts are gathered concerning protamine zinc insulin it is imperative to inform the patient that he

should not wait for the development of the well-known symptoms of an insulin reaction before treating himself Any vague or unusual symptom demands immediate treatment

Addendum

After this paper was submitted for publication there appeared papers by Wilder and Wright,¹ Lawrence and Archer,² and Jordan,³ drawing attention to the fact that the subject of reactions has been minimized These authors also recognized the hazard of the subtleness of a protamine zinc insulin reaction, and in their publications emphasize the importance of close surveillance of the patient

IS THE DECLINE IN TUBERCULOSIS ARRESTED?

Has the decline in the death rate from tuberculosis been stopped? Provisional mortality reports for 1936 raise this question

For many years past we have registered steady and rapid improvement in the mortality from this cause, so much so that we have been led to hope that, in the not too distant future, this disease would be relegated to a minor position among the causes of death, says the *Statistical Bulletin* of the Metropolitan Life Insurance Co Have we perhaps been over-optimistic?

Through the courtesy of State health officials the Metropolitan Life Insurance Company has received provisional mortality figures for tuberculosis for the year 1936 from 40 States Of these there were just 19 which reported a mortality for 1936 higher than that for 1935, and 19 which reported lower figures, two showed no change

Whichever way the balance will be found to tilt when final results for all the States are in, this is sure, that the margin of increase or decrease over the preceding year will be small Even if we do not have to record an actual rise, there certainly has been a definite check in the velocity of the decline in tuberculosis mor-

tality which has been going on continuously over a number of years past.

The question, then, arises as to whether the current status of the tuberculosis death rate is an aftermath of the depression Has there been an impairment in American vitality, which did not become manifest until the depression itself had lifted? Public health workers have feared that this very contingency might arise It is certain that the unfavorable tuberculosis situation which now confronts the country has not been due to any abatement in the efforts toward tuberculosis control, for there has been no let-down It is equally clear that what is now called for is an intensification of the work of those responsible for protecting the public health—and more particularly, even greater concentration on tuberculosis The record of the last 25 years in the attempt to control this disease has been so clear cut and favorable that there should now be no hesitation in bringing the effort to a successful termination But it will take years and much money and thought to do it. The present picture is an excellent corrective to any undue optimism which may have resulted from the rapid improvement in the tuberculosis situation in the last 10 years

Examination revealed an adult male of sthenic habitus. He weighed 141 lbs, and was 5'8" in height. Temperature 98.6, pulse seventy-two, and respirations twenty-four. General examination was negative. A fissure in ano was present. Blood pressure was 120/80. Urinalysis was negative. A blood count showed eighty per cent hemoglobin and 4,120,000 red cells. A diagnosis of inanition and fissure in ano was made. The patient was treated with local applications of silver nitrate to the fissure, and was advised to take sitz-baths and mineral oil. Heptogene tablets II t.i.d. was prescribed.

	Hgb	Red cells	Symptoms persist
2/4/37	84%	4 200 000	Symptoms persist
2/11	90%	4 420 000	Slight improvement.
2/18	100%	4,800 000	Marked improvement in general condition.
2/25	100%	5 110 000	All symptoms subsided. Patient weighed 145 lbs. The fissure has healed.

Comment Inanition, the result of overwork and poor hygienic conditions, produced symptoms of secondary anemia, although no anemia actually existed. The combination therapy prescribed over a period of one month alleviated the condition. The relief is probably temporary since the patient will undoubtedly suffer a recurrence unless he changes his mode of living.

CASE 2 D M, female, age twenty, was first seen on October 22, 1936 at which time she complained of pain in the right lower quadrant radiating to the back and groin and associated with nausea and vomiting. Her menstrual history was negative except for a miscarriage in July 1936. There was no history of dysuria.

Examination revealed a slightly built young adult, weighing ninety-two lbs. Temperature ninety-nine, pulse eighty, and respirations twenty-four. Blood pressure was 118/80. Head, neck, heart, and lungs were negative. There was tenderness in the right lumbar region and a definite feeling of fullness was palpated, but because of rigidity the exact nature of this could not be determined. X-rays of the abdomen disclosed a large right kidney. The left kidney was not visualized. On retrograde pyelography, the left ureter and kidney were found to be absent, and the right kidney was enlarged and ptosed producing a kink one half inch distal to the kidney. From these findings a diagnosis of congenital absence of the left kidney and ptosis of an enlarged right kidney was made. The patient was advised to wear a properly fitted support for the ptosed kidney, and she was placed on a high caloric diet.

1/20/37 No gain in weight. Patient still complained of lassitude and loss of appetite. Protomin

		insulin units V injected and high caloric diet continued	
1/28		After daily injections of protomin insulin weight increased to 101 lbs. 74% hgb 4 065 000 red cells Heptogene tablets II t.i.d. ordered	
2/4	76% hgb	4 085 000 red cells.	102 lbs
2/10	82% hgb	4 100 000 red cells	102 lbs.
2/17	88% hgb	4 350 000 red cells.	102 lbs. Protomin insulin discontinued because there was no weight increase after three weeks of this treatment
2/26	90% hgb	4 510 000 red cells	102 lbs Lassitude gone Feels well
3/1	90% hgb	4 500 000 red cells	102 lbs All symptoms subsided.

Comment It was believed that with increased weight the deposit of perirenal fat would be sufficient to hold the kidney in place. However, one is hesitant to discontinue the mechanical support in spite of the weight gain. Protomin insulin in association with the high caloric diet was responsible for the gain in weight. The combination therapy, however, raised the hemoglobin from seventy-six to ninety per cent, and for the past two weeks the patient has maintained her weight without resorting to other therapy.

CASE 3 N D, female, age twenty-eight, was seen December 11, 1936. She complained of pain in the left lower quadrant associated with a low grade temperature. She was treated five years previously for an ovarian disease. Her last menstrual period was two weeks prior to my first examination. Temperature 101, pulse ninety, and respiration twenty-four. Examination revealed a mass in the left lower quadrant which was tender. Peritoneal rebound was elicited. There was definite left rectus spasm. On vaginal examination the uterus was found to be normal in size, shape, and position. A large mass, the size of a grapefruit, extremely tender, was felt to the left of the uterus. Blood count reported 22,000 white cells and eighty per cent polymorphonuclears and twenty per cent lymphocytes. Smears for gonococcus were negative. A diagnosis of tubo-ovarian abscess was made, and the patient referred to Dr. Edward Horowitz for fever therapy.

1/28/37	After one treatment with hyperpyrexia mass was reduced to size of an orange. Patient felt tired weak and was unable to carry on her work (radio singer). She complained of no pain.		
	Hgb	Red cells	Heptogene tablets II t.i.d. prescribed.
2/4	69%	3 930 000	
2/10	76%	3 820 000	
2/17	82%	4 040 000	
2/26	86%	4 320 000	Patient felt stronger and much improved
3/5	90%	4 520 000	All symptoms have subsided
	90%	4 510 000	Mass was about size of a walnut.

Comment The secondary anemia in this case was probably the result of chronic suppuration. A repetition of hyperpyrexia

is stored in the liver, approximately 254 mg per kilogram of dry substance being present. For this reason there are many who regard the effects of liver therapy in the treatment of pernicious anemia as a copper effect which would agree with the theory that liver serves as a stimulant to bone-marrow. The copper content of gastrectomized animals will completely vanish from the liver, rendering this organ negligible in its effect on anemic animals. Bence¹² concluded therefrom, that the copper content of the liver was dependent upon the activity of a healthy stomach. The factor responsible for this has been termed the antianemic principle, and is believed to be a nitrogenous base, the exact nature of which has not been determined. It is developed in the gastric mucosa and travels to the liver where it is stored. A liver hormone which tends to stimulate the production of red cells has also been described. This hormone may very well be a combination of the intrinsic factor, and the extrinsic factor which is contained in certain foods. However, there are some who believe this hormone to be an actual secretion of the liver. It seems, from the experiments of Bence, that the former view is apt to be the correct one, for without the intrinsic factor the liver loses its function in the hematopoietic process.

Recently, experiments with calcium have proven that this element increases the body resistance.^{13, 14} The functions of calcium are manifold. It takes part in the formation of bone, decreases excitability of the nervous system, and diminishes exudation by decreasing cell permeability, and acts as an antispasmodic.¹⁵ In addition, vitamin B has been proven by Castle to take a great part in maintaining the hematopoietic system, for by withdrawing vitamin B from the diet he has been able to produce pernicious anemia and he has been able to cure this disease by its addition. He has, therefore, termed it the extrinsic factor.¹⁶

With the above factors in mind, it has become the custom to prescribe small doses of copper with iron in the treatment of secondary anemia. With this mode of therapy, the liver is shunted and the iron is free to be used directly for hemoglobin formation while the copper functions to stimulate erythrocytic activity.

The results obtained have been satisfactory to a certain degree. Machold,¹⁷ in 1934, prescribed a preparation containing 25 mg copper, 1 g ferric chloride, and 1 gram gastric powder, the latter being added to prevent gastric disturbances. He found that its effect on red cell stimulation was greater than on the hemoglobin stimulation. In the treatment of anemia in children, Lewis¹⁸ found copper and iron to yield satisfactory results, both clinically and symptomatically. Mills¹⁹ treated idiopathic anemias with iron, copper, and liver, and attributed the good results of the liver therapy to its high copper content. Copper, liver, and iron are now being used in most clinics to combat anemia.

In applying Buerger's principle to the treatment of secondary anemia, there is available iron which serves as a hemoglobin builder, copper, which acts to stimulate erythrocytic formation, liver, which contains the intrinsic factor, vitamin B as the extrinsic factor, and calcium, which acts on bone and cell permeability. Thus, when combining all of these, a *multiplicity* effect should result because of the different pharmacological points of attack. A preparation containing liver extract 24 gr, iron albuminate 166 gr, calcium gluconate 12 gr, two Sherman units vitamin B, and ten units vitamin G was selected. The combined small doses, in preference to large doses of a single ingredient, should, according to Buerger's theory, produce the desired effect.*

Case Reports

CASE 1 J K, male, age eighteen, was first seen on January 27, 1937, at which time he complained of lassitude, loss of vigor, and pruritis ani. Both parents are mutes, his father as a result of meningitis and his mother following scarlet fever. The patient made an uneventful recovery from poliomyelitis in 1931. For the past seven months the boy has been employed as a clerk and attending school at night. Lately he has been complaining of insufficient energy to carry on his routine, and more recently has suffered from an itch in the perianal region. The patient has not been constipated and there were no symptoms referable to the other major tract.

*This combination is now available as Heptogene.

Examination revealed an adult male of sthenic habitus. He weighed 141 lbs, and was 5'8" in height. Temperature 98.6, pulse seventy-two, and respirations twenty-four. General examination was negative. A fissure in ano was present. Blood pressure was 120/80. Urinalysis was negative. A blood count showed eighty per cent hemoglobin and 4,120,000 red cells. A diagnosis of inanition and fissure in ano was made. The patient was treated with local applications of silver nitrate to the fissure, and was advised to take sitz-baths and mineral oil. Heptogene tablets II t.i.d. was prescribed.

	Hgb	Red cells	Symptoms persist
2/4/37	84%	4 200 000	Slight improvement.
2/11	90%	4 420 000	Marked improvement in general condition.
2/18	100%	4 800 000	All symptoms subsided. Patient weighed 145 lbs. The fissure has healed.
2/25	100%	5 110 000	

Comment Inanition, the result of overwork and poor hygienic conditions, produced symptoms of secondary anemia, although no anemia actually existed. The combination therapy prescribed over a period of one month alleviated the condition. The relief is probably temporary since the patient will undoubtedly suffer a recurrence unless he changes his mode of living.

CASE 2. D M, female, age twenty, was first seen on October 22, 1936 at which time she complained of pain in the right lower quadrant radiating to the back and groin and associated with nausea and vomiting. Her menstrual history was negative except for a miscarriage in July 1936. There was no history of dysuria.

Examination revealed a slightly built young adult, weighing ninety-two lbs. Temperature ninety-nine, pulse eighty, and respirations twenty-four. Blood pressure was 118/80. Head, neck, heart, and lungs were negative. There was tenderness in the right lumbar region and a definite feeling of fullness was palpated, but because of rigidity the exact nature of this could not be determined. X-rays of the abdomen disclosed a large right kidney. The left kidney was not visualized. On retrograde pyelography, the left ureter and kidney were found to be absent, and the right kidney was enlarged and ptosed producing a kink one half inch distal to the kidney. From these findings a diagnosis of congenital absence of the left kidney and ptosis of an enlarged right kidney was made. The patient was advised to wear a properly fitted support for the ptosed kidney, and she was placed on a high caloric diet.

1/20/37 No gain in weight. Patient still complained of lassitude and loss of appetite. Protomin

	insulin units V injected, and high caloric diet continued	
1/28	After daily injections of protomin insulin weight increased to 101 lbs. 74% hgb 4 065,000 red cells. Heptogene tablets II t.i.d. ordered.	
2/4	76% hgb 4 085 000 red cells.	102 lbs.
2/10	82% hgb 4 100 000 red cells.	102 lbs.
2/17	88% hgb 4 350 000 red cells.	102 lbs. Protomin insulin discontinued because there was no weight increase after three weeks of this treatment.
2/26	90% hgb 4 510 000 red cells.	102 lbs. Lassitude gone. Feels well.
3/1	90% hgb 4 500 000 red cells.	102 lbs. All symptoms subsided.

Comment It was believed that with increased weight the deposit of perirenal fat would be sufficient to hold the kidney in place. However, one is hesitant to discontinue the mechanical support in spite of the weight gain. Protomin insulin in association with the high caloric diet was responsible for the gain in weight. The combination therapy, however, raised the hemoglobin from seventy-six to ninety per cent, and for the past two weeks the patient has maintained her weight without resorting to other therapy.

CASE 3 N D, female, age twenty-eight, was seen December 11, 1936. She complained of pain in the left lower quadrant associated with a low grade temperature. She was treated five years previously for an ovarian disease. Her last menstrual period was two weeks prior to my first examination. Temperature 101, pulse ninety, and respiration twenty-four. Examination revealed a mass in the left lower quadrant which was tender. Peritoneal rebound was elicited. There was definite left rectus spasm. On vaginal examination the uterus was found to be normal in size, shape, and position. A large mass, the size of a grapefruit, extremely tender, was felt to the left of the uterus. Blood count reported 22,000 white cells and eighty per cent polymorphonuclears and twenty per cent lymphocytes. Smears for gonococcus were negative. A diagnosis of tubo-ovarian abscess was made, and the patient referred to Dr. Edward Horowitz for fever therapy.

	After one treatment with hyperpyrexia mass was reduced to size of an orange. Patient felt tired weak and was unable to carry on her work (radio singer). She complained of no pain.	
	Hgb	Red cells
1/28/37	69%	3 930 000
		Heptogene tablets II t.i.d. prescribed
2/4	76%	3 820 000
2/10	82%	4 040 000
2/17	86%	4 320 000
		Patient felt stronger and much improved.
2/26	90%	4 520 000
3/5	90%	4 510 000
		All symptoms have subsided. Mass was about size of a walnut.

Comment The secondary anemia in this case was probably the result of chronic suppuration. A repetition of hyperpyrexia

treatment although advised was refused by the patient. By building up her resistance with the combination therapy she was able to return to work and carry on her daily routine. She may, however, eventually come to operation if fever therapy is not continued.

CASE 4 S H, female, age thirty, was first seen on July 12, 1936 at which time she complained of nausea and vomiting complicating a pregnancy of eight weeks. At the time of the examination the patient weighed 109 lbs and stated that she had lost fifteen lbs since the onset of her pregnancy. Examination revealed infected teeth, heart, lungs, and neck negative. Blood pressure 120/80. The uterus is enlarged to the size of an eight weeks gravidity with a definite area of softening. Urinalysis is negative. A blood count reported seventy per cent hemoglobin and 3,500,000 red cells. A diagnosis of vomiting complicating pregnancy was made. The patient was put to bed and calcium and glucose by injection, iron and copper by injection, and vitamin E by mouth were given.

Clinical Course Patient continued to feel nauseous during July, but the vomiting had stopped after one week of therapy. She was permitted to resume activity in the early part of August, and on the 18th had a uterine hemorrhage which was controlled by resorting to the above described therapy. Bleeding recurred one week later but stopped after two days. The Aschheim-Zondek test at this time was positive. The patient was kept in bed until September (fourth month of gestation). Her blood pressure was 118/80, hemoglobin forty-eight per cent and the red cell count was 3,200,000. The patient was put on iron medication by injection and by mouth, but no increase in hemoglobin was obtained. On January 30, 1937 heptogene therapy was instituted. At this time her hemoglobin was forty-six per cent.

2/ 6/37	52% hgb	3 440 000 red cells.
2/13	56% hgb	3 470 000 red cells.
2/20	59% hgb	3 450 000 red cells.
2/24	Spontaneous delivery of a living child	
2/25	70% hgb	3 520 000 red cells.
3/ 4	75% hgb	3 500 000 red cells.

Comment An increase of ten per cent in hemoglobin over a period of one month may not be upon first thought of much significance, but it must be remembered that with intramuscular injections and therapy with the heavy metals by mouth, no increase in hemoglobin was obtained after a period of four months. The rise to seventy per cent after delivery was attributed to concentration. The combination therapy given during her postpartum stay in the hospital

brought the hemoglobin up from seventy to seventy-five per cent.

CASE 5 E C, female, age thirty-three, was first seen on December 28, 1936 presenting a history of amenorrhea of one month's duration. General physical examination was negative. Vaginal examination showed the uterus to be enlarged to the size of a six weeks gravidity. A blood count reported ninety per cent hemoglobin and 4,450,000 red cells. Urinalysis was negative. Blood pressure was 140/80. A diagnosis of pregnancy was made.

	Hgb	Red cells	Heptogene tablets II, t.i.d., ordered.
2/ 2/37	76%	3,960 000	
2/10	80%	4 120 000	
2/19	80%	4 200 000	
2/24	89%	4 520 000	
3/ 6	91%	4 500,000	

Comment Secondary anemia complicating pregnancy appeared three months after onset of gestation. Treatment with Heptogene restored the hemoglobin to normal after three weeks.

CASE 6 C B, female, age thirty-three, was seen on January 26, 1937, complaining of fatigue, lassitude, and loss of appetite. The onset of symptoms followed childbirth on November 7, 1936. Following her first delivery fourteen years ago the patient was left with a third degree retroversion. She had two miscarriages after that. The uterus was kept forward with a Smith pessary during the first three months of this last pregnancy after which she continued to carry normally, and delivered spontaneously. She had scarlet fever in early childhood which left her a deaf mute. Examination revealed a well-developed adult weighing 120 lbs. General examination was negative. Vaginal examination disclosed a third degree retroversion and a second degree rectocele. Urinalysis was negative. Blood count reported seventy-four per cent hemoglobin and 3,720,000 red cells. A diagnosis of inanition was made, and Heptogene tablets II t.i.d. was prescribed.

	Hgb	Red cells	Symptoms of fatigue and lassitude gone.
2/ 2/37	78%	4 200 000	
2/11	84%	4 420 000	
2/24	90%	4 440 000	

Comment Secondary anemia, the result of inanition, following pregnancy, cleared up after three weeks of combination therapy.

CASE 7 C K, age eighteen, was referred to me with the following history. She had been first seen on January 20, 1937 at which time she complained of headache, dizziness, nausea, and vomiting. Since her last menstrual period, three weeks prior to her first visit, she had been bleeding profusely. Her

past history was negative. General examination revealed a well-developed female presenting a marked pallor of the mucous membrane of the conjunctiva and lips. Her heart and lungs were negative. The uterus was small, anteverted, and freely movable. There were no masses palpable. The adnexa were negative. The urine was negative. Blood count reported forty-nine per cent hemoglobin, 2,400,000 red cells, 9,200 white cells with a normal differential. A diagnosis of functional bleeding was made. The patient was ordered to bed and placed on liver extract and iron medication by injection.

Clinical Course On the outlined regime the bleeding subsided, and by February 19, all symptoms had disappeared. Her hemoglobin at this time was forty-eight per cent. She was advised to take Heptogene tablets II t.i.d. By March 5 her hemoglobin rose to sixty per cent and the patient was symptom free.

Comment In this case the secondary anemia, the result of functional uterine bleeding, did not respond to liver and iron by injection. Combination therapy brought the hemoglobin from forty-eight per cent to sixty per cent after one month of treatment.

CASE 8 H G, female, age thirty, was seen on February 6, 1937 complaining of pain over the frontal region, overweight, and palpitation. She had been on thyroid medication for the past year, taking one grain three times daily, and for the past few months had been complaining of the aforementioned symptoms. Examination revealed a well-developed individual 5'2" in height and weighing 156 lbs. Nasal mucous membranes were pale and swollen. A small nasal polyp was present. Heart rate 100, no enlargement or murmurs. Girdle obesity was marked. Urinalysis was negative. Basal metabolism was reported minus five. Blood count reported ninety per cent hemoglobin and 4,500,000 red cells. A diagnosis of vasomotor rhinitis and obesity was made. The patient was treated with adrenal cortex, grains III t.i.d. Thyroid grains I t.i.d. and Heptogene tablets II t.i.d.

Clinical course On February 27, after three weeks of treatment, the patient had lost five pounds. There was no palpitation and the heart rate was seventy-eight. The nasal symptoms had subsided. The patient was advised to continue the therapy.

Comment Copper and iron, in the form of combination therapy, was given in this case in accordance with Hesse's theory, and after two weeks the palpitation and rapid heart rate had subsided.

CASE 9 B K, female, age twenty-eight, was seen on January 28, 1937 having no complaints but anxious to lose weight. Two years ago she had been given thyroid medication and developed symptoms of avitaminosis with severe pain in both legs and arms. Her basal metabolism rose from normal to plus twenty eight. The patient was hospitalized, and after ten days of rest was discharged. Her only present complaint was that of swelling of the legs. Examination revealed a heavy set, 5'2" individual weighing 152 lbs. Pretibial edema present. Heart and lungs were negative. Blood pressure 100/80. Urinalysis was negative. Blood count reported eighty-four per cent hemoglobin and 4,140,000 red cells. Basal metabolism was minus ten. A diagnosis of hypothyroidism was made. Patient placed on a 900 calorie diet, thyroid gr ss t.i.d., and Heptogene tablets II t.i.d.

	Hgb	Red cells	
2/ 6/37	86%	4 460 000	148 lbs.
2/25	90%	4 520 000	144 lbs. Blood pressure 104/80

Comment After four weeks of thyroid medication the patient showed no signs of intoxication similar to that suffered two years ago. Whether iron and copper acted to prevent these symptoms, in line with Hesse's theory is questionable. Further study along this line, however, is indicated.

Conclusion

The author wishes it to be understood that secondary anemia and its associated symptoms is a complication of an existing pathological state, and that such a disease

CHART I

a - % Rise in Hemoglobin (Dare)
b - % Rise in R.B.C. (10%-500,000)

must be eliminated to establish a cure. Likewise, when unhygienic surroundings serve as the etiological factor in inanition, therapy will only be transitory pending the eradication of the cause. The treatment of the symptom can only be advised as an adjuvant in the care of the disease.

In all the cases observed, the symptoms of lassitude, fatigue, loss of appetite, etc., cleared up after two weeks of therapy. The rise in hemoglobin was prompt, and in some instances an increase of ten per cent was recorded after two weeks (see chart). The increase in red cells was not as marked. However, after one month

most cases showed counts of approximately 4,500,000 red cells.

It is unfortunate that the number of cases studied did not permit comparison in controls so that the conclusion one arrives at is that the treatment of secondary anemia complicating inanition, pregnancy, chronic suppuration or bleeding met with highly satisfactory results with the combination of the hematopoietic drugs in compliance with Buerger's theory. The last two cases presented while other than secondary anemia, are included because they serve to confirm Hesse's theory.

TO UNKINK THE JURY'S BROWS

The puzzled expression on the faces of jurors and lawyers while a physician was testifying prompted a Jackson Heights physician to write a book.

The physician, Dr Philip Palew, collaborated with Isidore Halpern, an attorney, in the preparation of the volume.

The book, the physician's first publication, is intended to give lawyers or anyone interested in medical terms an idea as to what actually lies beyond definitions of these terms, says a Long Island City newspaper.

Dr Palew is associated with the orthopedic departments of Queens General Hospital, St. John's Hospital, Long Island City, and Willard Parker Hospital and is an instructor in orthopedic surgery at New York University College of Medicine.

"The Attorney's Guide to Medical Terms," is the title of the book.

Dr Palew was prompted to write the book in answer to many questions put to him by lawyers.

He and Mr Halpern did not attempt to write a learned and scientific tome on medicine, but attempted to "tell in plain English" the meaning of various phrases

to those who may be interested in a better understanding of medical phraseology.

There is scarcely a trial at which the words, "Tell it to the jury in plain English, Doctor," are not uttered by the judge or lawyer when a physician is on the witness stand and Dr Palew and Mr Halpern as they worked on the book kept those words in mind.

The authors in the preface state that the difficulty is that the physician on the stand, when he is being counselled to use plain English, is using those words which to him are plain and understandable.

The duty, therefore, according to the authors, evolves upon counsel to simplify and reduce to understandable terms, complicated medical terminology.

And Dr Palew and Mr Halpern feel that if their book is of any help to the lawyer or any person interested in a better understanding of medical terminology, the years spent in its preparation have served a useful purpose.

Miss Mary Lorenc of the anatomy department of the New York University College of Medicine is credited for the drawings in the book.

SYSTOLIC MURMUR

Symptomatic Importance in Heart Muscle Weakness

GEORGE ZUELZER, M D, *New York City*

Clinical medicine requires a diagnosis not to be based on merely one given symptom but on as many symptoms as can possibly be found. This requirement, however, is most frequently disregarded, as I shall prove, in cases where a cardiac diagnosis is based on the systolic murmur exclusively. Sahli-Bern, in his well-known textbook of "Clinical Diagnosis," advises that a cardiac murmur should be considered of no diagnostic value, merely an accidental incidence, if there is nothing else to prove that a valvular disease actually exists.

The fact that there may be different causes for the manifestation of a systolic murmur, is a knowledge well-established. Bystritsky,¹ in his recent paper on functional cardiac murmurs, divides such murmurs into muscular murmurs, associated with some disorder in the myocardiac function of contraction and tonicity, and accidental murmurs which, while not related to myocardiac function, may be due to a variety of etiologic moments. This author investigated the state of myocardiac function in 583 cases of functional murmur (located at the apex), and reports that in eighty-two per cent of these cases there was some disorder in the myocardiac function noticeable. In another group of cases in which the murmur was audible at the base, the myocardiac function appeared to be disturbed in twelve per cent of all cases only. Unfortunately, there is no indication as to the method by which the myocardiac disturbance had been established.

Before entering into a discussion of the above statements, I shall endeavor to briefly discuss the origin of the first systolic sound. Leroy Crummer's² theory is generally accepted, it says

The cause of the first sound of the heart seems to be accepted as a physiological fact, all agree in stating two factors, muscle contraction and auriculo-ventricular valve tension. The first sound begins during the time of total closure, that is, when there is no movement of blood within the chambers,

thus, the idea seems substantiated that almost the entire first sound is a result of tension of both valves and muscle.

According to Geigel³ a sound is produced by disturbing the equilibrium of an elastic and sound-producing body suddenly and one at a time. With a murmur, the equilibrium is disturbed repeatedly for a longer, or shorter, period of time, however.

According to Crummer, increased volume of muscle in the left ventricle always gives the character of sound which has been described as booming, while the snappy first sound of mitral stenosis is explained as being due to preponderance of valve tension in the sound. These phenomena are in accordance with Geigel's law.

The reverse application of this law, e.g. its relation to the origin of cardiac murmurs in cases of weakening of the cardiac muscle, has not met with the interest to which it appeared entitled. Obviously, murmurs must be heard instead of a sound when the cardiac muscle is weakened, e.g. when its contraction is not sufficiently strong to produce the sound. It seems to me as though Bystritsky had not been fully aware of the definite relation between the strength of the contraction and the manifestation of the murmur, which I reported some years ago. Bystritsky, on one hand, claims that certain cardiac murmurs are due to some disorder in the myocardiac function of contraction and tonicity (and he is quite right in stating that this murmur becomes audible only with the patient lying down), but on the other hand, he obviously contradicts himself in regard to his own theory of myocardiac function, by stating that this murmur is never intensified by bodily exercise. I should say that the opposite holds true, and I say this on the strength of my own experiences which stretch over a period of twenty years, and include several thousand cases.

With the primary disorder in the

cardiac function, one hears a soft murmur preferably at the apex, but practically all over the heart as soon as the patient is in a horizontal position. In the upright patient, the sounds are normal despite some mild cardiac weakness, when arising, the patient performs the change of position but slowly, thereby excluding all physical strain exerted by a change of position, then the cardiac sounds appear to be quite normal. This difference is of great diagnostic importance, murmurs, more or less loud, become manifest upon physical exertion, (for instance, ten knee bendings)

In opposition to this systolic muscular murmur there is the murmur which is prompted by an insufficient auriculo-ventricular valve. The first cardiac sound originates simultaneously in both chambers during the time of total closure, according to Geigel, there is but one systolic heart sound. If, because of the absence of total closure (as is the case with mitral insufficiency), no sound is produced in one chamber, the other chamber is hampered in its endeavor to achieve a complete and sudden closure by its neighbor, so that no pure sound but merely a murmur can be discerned. This murmur will be audible in the patient both in a vertical or horizontal position, it may, however, vanish when the patient lies down. Of course, the manifestation of an organic murmur is always depending on the blood flowing through a narrow spot at a definite speed, and this speed is always increased physiologically in the upright patient. Thus it may well happen that in a case where there is slight mitral insufficiency, e.g. when the valvular insufficiency manifests itself only by a strain on the heart, no murmur will be heard in the patient when assuming a horizontal position, and the murmur will not become evident unless the velocity of blood circulation is sufficiently increased which phenomenon takes place as soon as the patient assumes a vertical position.

It is a knowledge well-established that in the animal system there is a physiologic increase both in the pulse rate and in the blood pressure when changing one's position from horizontal to vertical. The only exception, according to Francis Benedict, is given by the elephant. It is very likely that the change of position effects an in-

crease in the adrenalin secretion. It is conceivable that the sudden development of a higher tonus should follow as a reaction to the relaxation which a large part of the muscles have been experiencing during a bodily rest. The individual rises, and automatically demands an additional supply of energy which is immediately furnished. This additional supply of energy occurs probably in the form of dextrose effected by an increase in the adrenalin secretion which in turn is due to muscular activity. However, the adrenalin is not only responsible for the mobilization of dextrose by way of adrenalin, the latter simultaneously increases both the blood pressure and the pulse rate.

While in a normal individual the diminished tonus of the heart muscle—according to Geigel—may be sufficiently strong to produce the normal first cardiac sound, the tonus, under pathologic conditions (for example, through an infection) may be decreased to such an extent that merely a murmur is effected by the weakened contraction in the horizontal patient. The stronger tonus in an upright individual will suffice in producing a normal sound, however. The vanishing of the systolic sound stands in opposition to what happens in some instances in mitral insufficiency, as stated above, this phenomenon is to be regarded as the first symptom of cardiac insufficiency—as the expression of a hypotonia of the cardiac muscle. It is obvious that the manifestation of such a cardiac weakness is preferably observed as a symptom in acute infectious diseases. Roy Scott⁴ has but recently stressed the diagnostic significance of such cardiac murmurs in younger individuals as being indications of some cardiac lesion due to rheumatic infections. Lederer and Stolte have observed the presence of this systolic murmur in children suffering from scarlet fever, however, they have observed it only in children who are bedridden, and did not trace the sound in the children when assuming a vertical position. I myself have made the observation that in children suffering from scarlet fever, the systolic murmurs would vanish upon changing their position from horizontal to erect, so that there cannot be any doubt as to these forms of murmur being of perfect

identity The above-named authors have observed the presence of said murmur during a mild epidemic in 704 of all cases, and they arrived at the conclusion that these murmurs were effected by a decrease of the cardiac tonus which in turn had been prompted by the scarlet fever infection A similar decrease of the cardiac tonus has been described as being proper to cases of diphtheria infection Stejskal,⁵ in his experiments on dogs, was able to demonstrate that diphtheria toxin, introduced by way of injections, produced a decrease of the vasomotor tonus as well as of the cardiac tonus The murmurs ascertained in the scarlet fever children vanished slowly so that these children could be dismissed after eight weeks as completely cured, we know, however, that the cardiac muscles are more or less afflicted by the disease, and that it is merely a sheer impossibility to deduce from the clinical picture to the anatomic state Thus I believe to be justified in including such cases as "border-line cases" in the group of cases marked by a weakness of the heart

The theory according to which such murmurs originate from a decreased cardiac tonus, has been interestingly confirmed by experiments performed by Lederer and Stolte By administering faradization to one part of the body they achieved an increase in the peripheral pressure, thereby causing a temporary disappearance of the systolic murmur Schliepe,⁶ in analogy to these experiments, proved that in order to facilitate differential diagnosis between the atonic (or, better, hypotonic) murmur and the cardiopulmonary murmur in children, one may resort either to a physical irritation, or to a compression of the abdominal aorta, or to the lifting of the legs Under such measures the hypotonic murmurs vanish because of the passing increase of the blood pressure, as would also be the case with faradization or with changing to an upright position All of these measures cause the cardiac muscle to cross the tonus threshold so that normal sounds are produced once again

It is the same with adults, the lifting of the legs, or the compression of the abdominal aorta has a differential-diagnostic value equal to that in the case of children, but this applies only to mild

cases of cardiac hypotonia, e g where the systolic murmur is heard in the horizontal individual exclusively In more serious cases, e g where the murmur persists also in the upright patient, the increase of blood pressure effected by the above-mentioned measures is not sufficiently strong to permit of producing normal sounds The murmur may be changed into a normal systolic sound in such cases, however, by injecting adrenalin⁷ or eutonon

Potain has furnished an explanation of the above-mentioned cardiopulmonary murmur and the extra-cardiac systolic murmur He presumes that the heart, due to the decreasing volume during the systole, causes a negative change in the intrathoracic pressure, especially in the region close to the heart, in other words, that it exerts a systolic aspiration on the lungs, thereby producing a murmur This theory was established as a fact by experimental research The tender tissues in children yield most readily to this phenomenon, of course This goes to prove that the systolic murmur has a definite cause, and for that reason may not be regarded as being an accidental incidence

Anemia does not cause an accidental murmur, if it is not caused by constitutional diseases but only by an acute loss of blood I once saw a man who, while otherwise quite normal, had developed a strong anemia due to hemorrhoidal hemorrhages (35 per cent HB) The blood picture was entirely normal The anemia had occurred in a very short time There was no murmur, neither in a horizontal nor in a vertical position, not even after bodily exertion The so-called anemic murmurs always prove to be of a hypotonic character, the insufficiency of the cardiac muscle causing this systolic murmur is a constitutional factor as much as is the anemia This anemic murmur vanishes quickly upon introduction of the afore-mentioned measures, while the anemia may persist for a much longer period of time I definitely state that there are no other accidental murmurs, except perhaps in some rare anatomic anomalies which are of no practical importance

As regards the etiology of the anorganic myocardial or functional systolic murmurs there are mainly two causes respon-

sible for these cardiac disorders—infections, both acute and chronic, and physical overstrain. Of the infections, it is the influenza and, preferably, the chronic grippe which play the leading parts today. I am willing to concede that it may at times be rather difficult, even impossible, to differentiate between hypotonic murmurs and systolic-mitral murmurs, when, for example, such characteristic signs as the accentuation of the second sound, etc., happen to be absent, while the congestion of the liver may be present in either case. I find myself to some extent in accordance with Bystritsky in stating that the myocardiac function appears to be disturbed in hearts showing hypotonic-systolic murmur, and that the diagnosis of a decreased cardiac tonus is undoubtedly of greater importance than that of eventually accidental murmur which may happen to be present at times, but holds no diagnostic value. We have now seen that the majority of cases of “accidental

murmur” are due to functional changes of the cardiac muscle, thereby proving that there actually exists no accidental murmur, and that the few cases in which we happen to be unable to ascertain the cause of the systolic murmur, also belong with the general group. Thus, I would propose that the term of “accidental murmur” may be abolished as non-existent, and therefore regard every finding of a hypotonic muscular murmur as the very first symptom of a heart weakness which may lead to an irreparable heart failure sooner or later.

“BACK FROM THE DEAD”

That, at any rate, is the engaging title the daily papers put on the account of Dr Sebron C Dale, an intern in the University of Pennsylvania Graduate Hospital, who miraculously recovered after his head was nearly cut off by an insane patient. This strange story of a man who had his throat slashed severely two years ago and was believed dead, only to recover completely, was related to the American Laryngological Association and the man himself appeared as the living witness on May 31 at Atlantic City.

The story was told by Dr G B Wood of the ear, nose and throat department of the same hospital, as an unprecedented example of perfect teamwork between the various hospital factors.

A demented patient sneaked up behind Dr Dale and slashed him three times across the throat with a razor on Nov 2, 1935. The jugular vein and carotid artery were severed, the larynx opened up, some of the vocal cords were severed on one side, and all the muscles and nerves on one side of the jaw were cut. The head itself was all but severed.

Dr Dale staggered to the surgical dressing room on the same floor on which he was attacked. There a fellow intern seized him, stretched him out on the floor, used his

fingers in an attempt to check the copious flow of blood, and called for help.

There were some sterile hemostats in the surgical dressing room, and these later were snapped onto the ends of the severed blood vessels.

By this time, five minutes after the attack, Dr Dale apparently had ceased to breathe and no pulse action could be detected.

An operating room had just been prepared for an appendix operation, with surgeons and nurses ready, and all instruments sterilized and laid out. This room was commandeered for an emergency operation on the wounded intern, and surgeons thus were able to operate immediately, whereas two or three hours otherwise would have been required to prepare for the operation.

Dr Dale's type of blood already was known, and while another doctor in the hospital having the same type of blood was being prepared for a transfusion, a vein in one of the wounded intern's legs was opened and salt and glucose solutions were pumped into the blood stream.

After blood from the veins of the other physician was pumped into those of Dr Dale, the latter's pulse returned and he began breathing. Surgeons then sewed the severed ends of veins and arteries

AN ATTACHMENT FOR USE IN CONJUNCTION WITH THE SCALPEL

F M AL AKL, M D, *Brooklyn*

Some surgeons depend upon the scalpel exclusively for cutting. The scissors are taboo and in jest, branded as a gynecologist's instrument. The mass of operators however, make constant use of the scissors. They presumably see no particular advantage in taking the chances of injuring underlying structures while severing layers of tissue with the knife, or opening into body cavities. The preferability of cutting with a sharp blade, without crushing the edges of a wound makes the scalpel the instrument of choice. The scissors nevertheless, possess the decided advantage of being easier to manipulate. It further combines a cutting instrument with one capable of separating layers of tissue. Through the adapter herein described, the scalpel becomes modified to advantage and may in part supplant the scissors.

The attachment in question is a triangularly shaped spoon with a shallow longitudinal groove to accommodate the tip of the knife's blade. The handle of the spoon is a folded plate of steel through which the blade of the knife may slide and lodge securely (Fig 1).

Ordinarily, in cutting fibers of muscular aponeurosis or fascial sheaths, the closed curved scissors are introduced beneath the fascia through a small nick, opened to separate the fascia from underlying structures, then withdrawn and cut with. With the modified knife, (Fig 2) the process becomes greatly simplified.

Once the spoon of the knife is introduced through the nick in the fascia, the operator may safely proceed to push the knife along the direction of the desired incision, and as with a plough, the structures over the spoon are cleaved. The peritoneal cavity may be opened as easily with the modified knife. The peritoneum is nicked with the belly of the modified knife between clamps in the usual manner (Fig 3). The spoon is then introduced through the aperture and as its tip glides under the inner surface of the parietal peritoneum, the blade cuts through the structures, giving access to the cavity through the desired opening.

The same technic may also serve in opening the dura, the pericardium, or opening the ureters or biliary passages for the removal of calculi. The modified knife may further be used for all purposes of ordinary cutting such as fibrous bands, ligatures, etc. The tip of the adapter may be employed for teasing of tissue as in isolating the cystic duct from the gall-bladder pedicle, or for reflecting the peritoneum to demonstrate the uterine arteries before ligation, etc.

The modified knife presents three distinct advantages over the scissors, viz economy of time, economy of instruments, and added safety.

Inasmuch as two acts—the act of separating and the act of cutting—are performed by the same stroke, it follows that only half of the usual time is required.

Fig 1 Attachment, special blade, and standard Bard-Parker handle No 3

Fig 2 Blade and adapter attached to handle, ready for use

In performing a hernioplasty, for example, one can save time by simply hooking the intercolumnar fibers under the tip of the spoon (Fig 4), and immediately proceeding to incise the aponeurosis, instead of introducing a grooved director underneath the fibers of the external oblique then running the scalpel down the groove. Again, instead of using the scalpel to nick the peritoneum, introducing a sponge-stick to keep the viscera out of the scissors way, then cutting with the scissors, the modified knife takes the place of the three instruments, and performs the operation more quickly and gracefully. The modified knife, always underneath the structures it severs, leaves the operative field clear, and over the gliding tip of the spoon, the bladder fold may be detected and spared, a blood-vessel sighted and ligated or avoided, and adherent viscera may be separated from the abdominal wall, clearing the way for the blade.

The value of this knife and the smoothness with which it functions, depends upon the acuity of the cutting edge. A dull blade must never be used. Most surgeons throw a dull knife away while operating and simply ask for a fresh one, often to throw away the second one. Few take the trouble of finding out why the knife is dull. In recent experiments conducted with the cooperation of one of the changeable blade manufacturing com-

panies, I found out repeatedly that boiling ruins the edge. I have experimented with blades made of different grades of steel, with plain blades and with metal plated blades, and used blades honed by different processes, yet the blades invariably became dull after boiling. The fact that boiling is the easier and quicker method of sterilization seems to account for the popularity of the method with operating room nurses. Some nurses seem to entertain the notion that if cutting instruments are boiled for five minutes only, the edges are not affected. My experience has been however, that boiling even for few minutes is enough to dull the blades appreciably. I have suggested that manufacturers prepare sterile blades in sterile wrappers by handling the steel aseptically from the moment it leaves the furnace until delivered as blades on the operating tray, but because of certain technical difficulties this seems impossible, under our present economic set-up, without a prohibitive increase in the cost of production. Thorough washing of the blades with soap and water after removal from the wrapper, to remove the greasy coating, followed by immersion in phenol and alcohol respectively is as good a sterilization method as any with the advantage that blades sterilized in this manner remain sharp.

UNDULANT FEVER (BRUCELLOSIS)

Difficulties in Diagnosis and Treatment—A Supplementary Report on Fifty-One Cases with Observations on One Hundred and Twenty Additional Cases

HAROLD J. HARRIS, M.D., *Westport*

In 1934 I made a preliminary report describing my experience with fifty-one cases of brucellosis, acute and chronic.¹ Some of these patients have now been under observation for nearly four years and the remainder for more than two years. It now seems possible to evaluate the status of these cases and to draw conclusions, tentatively at least, as to the efficacy of treatment. Twenty-seven have remained well, after one or more courses of B abortus vaccine (53%), eleven have been greatly improved since vaccine therapy (21%), six have been improved but subject to mild relapse (11%), three refused treatment (6%), two had only intravenous typhoid vaccine with no improvement (4%), and two received little apparent benefit in spite of repeated courses of B abortus vaccine (4%). Long-standing chronic infections in elderly patients were especially prone to relapse. Relapses were seldom as severe as before vaccine therapy and usually yielded promptly to a few more doses of vaccine. There were no deaths.

Since this report, the observation and treatment of one-hundred and twenty additional cases has resulted in confirmation of most of the ideas set forth in the original report and has brought to light many new angles of this complex problem. The importance of prevention is being more and more appreciated and the disease is becoming recognized as of major importance. There is a growing appreciation of the fact that brucellosis can simulate a multitude of other diseases and syndromes.² The literature on many phases of the disease is making available a wealth of information which is bringing the subject out of the obscurity in which it existed only a few years ago. Articles on the general subject of brucellosis as well as on its occurrence in the fields of the various specialties are

now regularly appearing.^{3, 4} Still there is much to be elucidated in diagnosis and treatment.

The attempt to popularize the term brucellosis instead of undulant fever seems worthwhile. It seems inconsistent to physicians and laymen alike to call a disease any kind of fever wherein no actual fever may be observed. Undulant fever suggests an acute illness, not applicable to the chronic cases. Hughes discussed chronic brucellosis and terminology forty years ago.¹⁸

Epidemiology, Etiology, and Symptomatology will be referred to only incidentally since many have had repeated opportunities to read articles on this subject. I would prefer to discuss diagnosis (differential diagnosis especially) and to stress the form of treatment which has been used in this series of cases.

*Clinically, brucellosis is to be suspected in any obscure acute or chronic illness.*⁵ In my own experience it has simulated or caused the following staggering list of conditions: Anemia (primary or secondary), arthritis, ulcerative colitis, cholecystitis, appendicitis, toxemia of pregnancy, syphilis, grippé, typhoid, nephritis, pyelitis, cystitis, neuritis, tuberculosis, osteomyelitis, peptic ulcer, psychoneurosis, bronchial asthma, fibrinous bronchitis, abortion, salpingitis, infectious mononucleosis, perforation of abdominal viscus, unresolved pneumonia, low back pain (lumbosacral or sacroiliac strain, lumbar myositis), spondylitis, prolonged hyperhidrosis, chest pain suggesting heart or lung involvement, epistaxis, hyperglycemia and glycosuria resembling diabetes mellitus, skin conditions resembling erysipelas, pityriasis, scabies, seborrheic dermatitis, furunculosis—and "run-down states."¹¹

Like tuberculosis and syphilis, this infection may be so mild as to completely escape detection and, indeed, may exist

Read before Staff Meeting of the Champlain Valley Hospital, Plattsburg, March 9, 1937

in thousands of patients in so minimal a degree that the patient never seeks medical advice. This conception is extremely important. Without it we cannot hope to grasp the enormity of the problem created by *Brucella abortus*—for these mild infections may, at any time, become virulent, after months or years of latency.

A source of confusion, almost impossible to avoid, is the not infrequent co-existence of brucellosis and some other affection, well-illustrated by the illness of a man of fifty which began like a mild grippe, after a week of which there occurred a massive pleural effusion. His blood showed a low degree of agglutination with *B. abortus*, his skin test was strongly positive—and his pleural fluid showed tubercle bacilli on guinea pig inoculation. Following removal of fluid, radiographs showed no evidence of tuberculosis and sputum was negative, several months later parenchymatous changes in lung were apparent, which may have been due to either organism—for I have clinical evidence that *Brucella abortus* may attack lung itself. I still do not know which infection was first in appearance or effect but they did coexist, perhaps neither one was of clinical degree until it was flared up by the other—or both may have been quiescent until flared up simultaneously by grippe.

Diagnostic methods of a high degree of accuracy have been developed but it is unfortunate that blood agglutination tests alone have been so greatly emphasized. In acute brucellosis the so-called characteristic agglutination is obtained, often fairly late in the course of the disease, as in typhoid. Early in the course agglutination with *B. abortus* may occur in low degrees of dilution or not at all. Blood agglutination may remain negative throughout the entire course of the disease.^{8, 7, 8, 15} Alice Evans' personal experience probably would be repeated in others if the effort were made. Her blood agglutination tests were negative in all dilutions but *Brucella abortus* was isolated from her blood stream, and a focus found in her gall-bladder at operation.⁹ A partial agglutination with *B. abortus*, in patients who present a clinical picture of brucellosis, is just as significant as is agglutination in higher dilutions of the serum. To ignore this point

is to overlook a majority of the cases of brucellosis that come under our observation—which is exactly what I did for many years. Twenty of my cases showed a negative blood agglutination, in most instances on repeated tests. Eighty-six showed "partial" agglutination, that is, blood titers of 1 10, 1 20 or 1 40. Fifteen showed so-called characteristic agglutination—1 80 or higher. No case was as startlingly significant as Alice Evans' but one patient whose temperature range was as high as 107.2°F at intervals over a period of seven years never showed an agglutination titer higher than 1 40. There seems no occasion for surprise or doubt in these statements. The agglutination test for brucellosis is not a test for the presence of organisms in the blood, of course. Like the Widal test it is only for determination of specific agglutinins in the blood.

The question naturally arises as to how brucellosis can be diagnosed in the absence of agglutinins in the blood, even on repeated tests. There are two other procedures—the intradermal test and the opsono-cytophagic test of Huddleson. I have had no experience with Huddleson's test because of lack of laboratory facilities but it is receiving more and more favorable comment as a diagnostic procedure.^{6, 10} The skin test^{10, 11, 12, 16} has proven of great value but too much confidence should not be placed in it since a positive test, *per se*, does not prove the existence of active brucellosis but may only indicate that the patient has become sensitized to killed *Brucella abortus* organisms because of previous exposure to this live organism. Therefore, just as in the presence of only a partial blood agglutination, the diagnosis cannot be made on the basis of a positive skin test alone, unless the patient presents a clinical picture of acute or chronic brucellosis. Also, the degree of the skin reaction must be interpreted with caution to avoid errors in either direction. A large red swelling followed by local sloughing at the site of injection is a positive test, of course, but it does not indicate any more as to the presence of an active infection than does the small elevated nodule the size of a split pea, read four days after 0.1 cc of a killed suspension of *B. abortus* (2000 million organisms per cc.)

is injected in the superficial layers of the epidermis. This is the same vaccine that is used for treatment. The degree of local reaction is a valuable guide however in predetermining the sensitivity of that patient to subsequent intramuscular doses of the vaccine, used therapeutically, after diagnosis is established. One knows that small initial doses are indicated, until desensitization is accomplished, in patients exhibiting violently positive skin reactions. Huddleson¹² uses a filtrate of a mixed strain of *B. abortus* for skin tests (available under the name *Bru-cellin*) and for determining sensitivity of the patient to the filtrate which he uses in treatment. In three instances an interesting result of a markedly reacting skin test has been the complete freedom of the patient from symptoms of brucellosis following the subsidence of the skin reaction, no further vaccine having been used. Rarely will the skin test be negative when the blood test is positive, this happened in two instances. When skin tests are doubtful and when the clinical picture is not quite sufficiently definite (with or without positive skin and agglutination tests) to establish a clinical diagnosis of brucellosis a few therapeutic test doses of the vaccine will usually clarify the diagnosis, a rise to a moderately high level of the blood agglutination titer accompanied by clinical improvement helps to confirm the tentative diagnosis, under these circumstances. Obviously careful physical examination and all other indicated laboratory procedures are more than ordinarily necessary in such doubtful cases. Skin test should not be performed prior to blood agglutination tests lest confusion result from the formation of agglutinins which usually follow the skin test even in a patient free from brucellosis. In many respects the skin test for brucellosis is comparable with the tuberculin test in routine use—it is significant only in the presence of other evidence of the disease, clinical or laboratory.

Apparently the chronicity of brucellosis is still questioned by some, although by now there is ample evidence of its frequent occurrence. One of my cases furnished an especially striking example of what a chronic case may be.¹ A woman of thirty aborted three times but was

never otherwise ill with acute symptoms of fever, culture of lochia following the third abortion yielded *B. abortus*, blood agglutinated with *B. abortus* in a 1:160 dilution of the serum.

The anemia, so often present in chronic brucellosis, deserves special discussion. While a peculiar white or oyster-grey color occurs commonly, not all of these patients exhibiting this peculiar pallor are anemic, while a profound or slight degree of anemia may exist in others with variable skin pallor. A mild degree of secondary anemia is the common finding and yields readily to adequate doses of iron. In a few, the anemia is profound and very difficult to distinguish from pernicious anemia. In these cases treatment of the anemia with liver extract parenterally, at the same time that vaccine is given, seems essential. Parenthetically, I might say that liver extract intramuscularly seems to exert an influence for good in the treatment of the intractable chronic case of long-standing, regardless of the presence of anemia. This observation was also made independently by Meyer.¹⁴ Repeated red cell counts and hemoglobin estimations are essential, especially because anemia may develop in the midst of apparently successful treatment. Peculiarly, the vaccine will not bring about improvement in the blood picture unless treatment is aimed at the anemia coincidentally with vaccine therapy.

I have noted before¹ the marked prevalence of dental infection in brucellosis. Three-fourths of my cases have had one or more abscessed teeth. One woman had twenty-eight! Their removal seems absolutely essential if anything approaching cure is to be accomplished. I have been unable to prove whether or not the organism of brucellosis is the direct cause of these root abscesses. Dental study, including x-ray, even of the supposedly edentulous mouth, should be routine.

Confusion in differential diagnosis between brucellosis and tuberculosis may arise not only when the two coexist but in low grade infections with either organism, the signs and symptoms may be so nearly identical as to defy positive proof of either—fatigue, loss of weight, sweats, cough, and slight elevation of temperature, often with chest pain. It is not

rarely that cases of brucellosis are observed in tuberculosis sanatoria for weeks or months before the absence of actual tuberculosis is proven. The confusion with hyperthyroidism obviously also occurs.

Peptic ulcer either coexists with brucellosis in a surprising number of cases or brucellosis is the actual cause of ulcer in some instances. Epigastric pain and a more or less typical ulcer syndrome often occurs in brucellosis, in the absence of actual ulcer, as shown by operation and radiography.

Salpingitis due to brucellosis must always be borne in mind when the etiology is not otherwise clear. It is not infrequent and has been a source of error with gynecologists of the greatest ability.

Appendicitis may be so closely simulated in chronic or subacute brucellosis that operation will seem justifiable to the most conservative surgeon. I have seen eleven such instances. In most of them, the pain, tenderness, nausea, and low-grade fever recurred persistently until vaccine therapy was instituted, and then ceased. White cell counts were of no diagnostic help in such cases for, contrary to the generally accepted idea, leukocytosis rather than leukopenia occurred in the majority of these cases of subacute brucellosis as well as in the presence of other manifestations of the disease. Leukopenia often does occur in the chronic case however. It seems possible that some of the abdominal conditions, operated with a diagnosis of chronic or subacute appendicitis and in whom symptoms recur after operation, may well be due to brucellosis. It is conceivable, of course, that *brucella abortus* may invade the appendix and cause actual appendicitis.

Osteomyelitis is another evidence of the ubiquity of this organism. I have recognized but one case, but Kulowski⁴ has reported osseous and joint lesions in five cases. My patient had had three operations to drain both femurs. A subsequent acute pelvic condition, which I considered a likely ectopic pregnancy, led to the correct evaluation of both illnesses as brucellosis.

Orchitis is mentioned only because I have seen it but once in brucellosis, although it is stated in the writings of many to be a common complication.

Toxemia of pregnancy has occurred in several of my cases of brucellosis. Any organism that may directly attack the placenta, as does *B. abortus*, may well be a direct cause of toxemia because of its influence on placental hormone production alone. Blood and skin tests are a routine in my obstetrical patients with this in mind and because of the tendency to abortion.

Skin eruptions of brucellosis continue to be confusing. I have seen such marked similarity to pityriasis, erysipelas, and scabies as to render diagnosis extremely difficult. Therapeutic test doses of vaccine have often proven of value here.

Arthritis due to brucellosis is receiving the attention it deserves at the hands of workers such as Hardy, Kulowski, Simpson, and others. It may be very difficult to distinguish from arthritis due to other causes and undoubtedly accounts for some unexplained failures in treatment.

Psychoneurosis has been the erroneous diagnosis in many a case of brucellosis and will continue to be until we decide to rule out this infection as well as all other conditions before attaching this label to various conditions. I have seen much harm come from this error, when made by myself and others.⁵

Low back pain, with or without sciatic pain also deserves emphasis because it is occasionally a part of the symptom complex caused by brucellosis and therefore amenable to treatment.

Failure to convalesce normally following acute illnesses such as measles has been noted in patients with chronic low-grade brucellosis not previously requiring treatment, or exacerbations of mild cases often occur following intercurrent infections, such as may in tuberculous patients.

Diabetes has been simulated in brucellosis in a few of my cases in that glycemias and glycosurias have been noted and have disappeared along with other existing signs and symptoms, following vaccine therapy.

Injuries, such as sprains of joints, may result in symptoms and signs out of all proportions to the trauma, in patients with brucellosis, apparently due to localization of the morbid process in injured tissue, where it is apt to remain until specific treatment is instituted.

Conversely, it is obvious that errors in diagnosis may be made by the overenthusiastic physician in just the opposite direction to those discussed above, but careful study of all cases should obviate such errors in time.

I believe the effect of *B. abortus* vaccine is specific in most instances and that shock effect is of incidental consequence.

Treatment in all cases, except two, has been the administration of *B. abortus* vaccine, furnished by the Division of Laboratories of the New York State Department of Health. The two cases referred to were given typhoid vaccine intravenously with no effect except extremely unpleasant reactions. Dosage was varied to fit each case. Those demonstrated to be very sensitive, through noting unusually severe skin test reactions or in whom one therapeutic dose of vaccine was followed by undue local and general reaction, were given very small doses of vaccine until desensitization occurred. Only in one case of probably sixteen years duration were the reactions so severe that it seemed best to stop treatment even though definite improvement was noted. The usual initial dose was 0.3 c.c., intramuscularly, in the deltoid region. Subsequent doses were increased, decreased or repeated depending upon the local and general reaction, upon the clinical course of the illness, and upon the changes in the blood agglutination titer. The interval between doses was from three to seven days. Reactions, local and general, were allowed to subside before the next dose was given. Severe reactions were usually deliberately avoided, although some cases seemed to require definite reaction-producing dosage. If clinical and serological improvement was not evident within a reasonable time, intravenous dosage¹⁷ was resorted to (fifty-three patients were given from one to three doses intravenously, usually one dose of fifty million killed organisms). Reactions to the intramuscular route varied from a slightly lame arm at the site of injection to severe malaise, chills, and high fever. Intravenous vaccine usually produced sharp reactions but never, in any instance, anything approaching a fatal outcome although it was given to two patients past eighty, one of whom

had had a severe myocardial damage for many years. This patient made a spectacular recovery, although a small dose of vaccine intramuscularly still seems essential once monthly to maintain her resistance.

The number of doses of vaccine also was suited to the individual. A usual course was eight doses at about weekly intervals, followed by a few doses at fortnightly intervals, and then once monthly until many months had elapsed without sign of recurrence. When relapses occur in patients previously treated—and they do occur commonly—a few more doses of vaccine usually suffice to bring about remission, although a few patients show evidence of requiring this monthly dose for an indeterminate time.

My effort has been to secure clinical improvement with a steadily rising blood agglutination titer. *Clinical improvement almost invariably will keep pace with the rise in titer.* In a few patients a titer of 1:200 or even higher seemed essential to recovery. The average patient will show clinical response by the time the titer has reached 1:160 or 1:640. A few patients have made clinical recoveries with titer no higher than 1:80. It is my aim to keep the titer at the optimum level for that particular patient until clinical recovery has occurred, by frequent dosage, large dosage or intravenous administration, as may be necessary. A gradually lowering titer, after recovery, is considered all right, unless relapse occurs, when the effort to elevate the agglutination titer is resumed.

Acute cases are not treated with vaccine if their blood agglutination tests show a high titer since nature is accomplishing all that vaccine can be expected to do. Since relapse is almost invariably accompanied by a drop in titer, vaccine given at this point would be of value.

Brucellosis, in the vast majority of cases, is a self-limited disease only in that the acute stage limits itself (if the patient survives, and the death rate is probably not over one per cent—a fraction of one per cent if chronic cases are included in the mortality study). Some of these acute cases recover completely without relapse but I suspect that this fortunate group is small. The others go on in the

chronic phase of the disease, perhaps with minimal symptoms that never require medical attention but more often with fatigue, mental apathy, muscle or joint pain or any of a tremendously varied list of complaints and conditions. Some may never have another acute illness but many have repeated severe attacks over a period of years. It is for these cases and for the persistent chronic cases that vaccine accomplishes most.

The question of reinfection is still unsettled. I can only point out that recurrence of brucellosis has appeared to be most common in those farmers whose herds have repeatedly been swept by Bang's disease.

Foshay and his associates¹⁸ have shown horse and goat specific antiserum to be of great value in acute cases of brucellosis of less than four months duration. Intravenous neo- or sulfarsphenamine has been urged by several but has proven disappointing in the few patients to whom I gave it. Intravenous typhoid vaccine (true shock therapy) was a complete failure in the two cases to whom I gave it. With chemotherapy other than the arsenicals, I have had no experience.

Removal of the gall-bladder, in the presence of such a focus of infection may be essential in some instances. I have had apparent success in such cases by the use of six meter diathermy through the gall-bladder, in conjunction with vaccine therapy. Similar experience in salpingitis has been noted.

Of the 171 cases reported, 132 had treatment with B abortus vaccine, the remaining thirty-nine had inadequate treatment or no treatment. Of the treated cases forty-two per cent were clinically cured, thirty-six per cent were markedly improved. Results then were satisfactory in seventy-eight per cent. Eighteen per cent were improved to some degree. Three per cent showed no definite lasting improvement. It is, of course, possible that the last two groups comprised a few cases in which erroneous diagnosis of brucellosis were made. There were no deaths in the entire series.

No controls were possible, of course, these all being private patients. However, the thirty-nine untreated and inadequately treated case group serves as a fair index of what happens to these untreated cases. Thirty-two continue to have recurring symptoms of brucellosis—seven are either well or have symptoms the origin of which are indeterminable.

In this community no new cases have been noted among the non-farming population since pasteurization of milk was introduced in 1934.

Summary

Observations are made on one-hundred and seventy-one cases of brucellosis, fifty-one of which have been watched from two and one-half to four years. Differential diagnosis is stressed, with discussion of some of the most common and important diagnostic errors. Treatment with B abortus vaccine intravenous and intramuscular is discussed in detail. Diagnostic procedures are described.

Conclusions

1 Brucellosis is still not recognized in its full importance.

2 Diagnosis is still difficult, in spite of the three laboratory procedures, largely because of the multiplicity of diseases and syndromes simulated by brucellosis.

3 To ignore "partial" blood agglutination titers or to fail to do either the intradermal test or the opsono-cytophagic test is to overlook a majority of the cases of brucellosis that come under our observation.

4 Vaccine therapy gives great promise in the majority of cases if intelligently used, clinical recovery occurring in the majority of cases.

5 Vaccine may be used intravenously with reasonable safety if proper precautions are observed. Its efficacy seems proven in selected cases.

6 Relapses are common after vaccine therapy but rarely are they severe, usually yielding to a few doses of vaccine.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., Dr P.H., *New York City*

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Perversion or Madness

Young man, single, worker, suffered from mental conflicts due to homosexuality. Manic depressive, depressed type.

"My mind is not clear, not steady"
 Been treated much in a New England city. No result. Been advised by a physician, patient claims, to get married to a woman. This was almost unbelievable, or if true, it was bad advice.

His chief problem was to get rid of the homosexual habit and live with a woman "like everybody." Once, years ago, he actually cohabited with a woman, but under extraordinary circumstances and it never occurred again. He was boarding with a family and one day, when he and the housewife happened to be alone, she came to his room and enticed him to have relations. Patient was twenty-four years old and his temporary partner forty-eight. The second time he refused and since then she has hated him and has contributed largely to his misfortune by subtly spreading the news of his sexual condition. A man can have no greater enemy than a woman who offers herself in adultery to him and is rebuked.

This unique event in his life "convinced" him that he was able to have sex intercourse with a woman. He adds, though, that, while he could consummate the act, he was entirely indifferent to it. He had a feeling of disgust for the woman.

Influenced by public opinion, he felt unhappy over his homosexual inclination and feared and "hated" it much, although he greatly desired contact with persons of his own sex.

As a child he had slept with an older brother who tried successfully to debauch him. Once, when sharing his father's bed, it was the patient, then a mere little boy, who attempted sexual connection. Astonishingly his father who at first resented it and

punished him, later tolerated his boy's caresses.

Since that time he has known all sorts of men and for a whole year he frequently visited a house where several male homosexuals met daily.

Patient described himself as a passive and active homosexual and as one who in his childhood had always wished to be a girl. He used to put on female clothes and play like a little female.

He was a sickly child and probably much spoiled by his parents. He began to walk late, at five. The same with talking—and he also stuttered.

Physically this patient is in good health. His body is masculine, the genitals are well-developed, although the penis is smaller than expected. The pubic and chest hair is sparse. So is the facial hair, despite the fact that he shaves. His intelligence is between dull and average.

While his homosexual tendency has had its beginning as result of his childhood environment, it seems to be clear that this patient is not suffering from acquired homosexuality like the majority of his species. There must have been a strong congenital trend.

Therefore, it was a great risk to induce him to associate with a girl in wedlock. Such a union might have made both him and her extremely unhappy and wrecked their lives, as it often does.

For the last couple of years, because of his effort to reject his abnormal sex habits, he has had no sexual friendships, neither of one kind nor of another. There was no need, consequently, to take a decision. It was best for him to go about his business and try to be occupied with other matters. In fact, there was no necessity of getting

married at any time, since he really did not crave it, but wanted merely to make a concession "to the world"

Moreover, it was made clear to him that while homosexuality was not to be recommended, it could not be regarded—from a

physician's viewpoint at least—as immoral or objectionable. If a choice must be made between "going insane," no matter how mildly, and practicing an act which was regarded as unnatural, the latter alternative was undoubtedly to be accepted.

Refuge

In 1928 a woman of thirty, a lawyer's wife, herself an ex-journalist, having two children, came complaining of dull pains in the abdomen and nausea. She "cannot eat because the food repeats." The examination showed nothing positive or suspicious. She slept well.

She was on "tolerable terms" with her husband, she stated, and quite happy with the children.

But at the second visit she insisted that she was restless, she could not stand the noise in the street and was "bothered by a choking sensation."

She was afraid of something indefinite, which she later admitted amounted to a "fear of insanity." She had "lost interest" in most things that had been dear to her. She was asked again whether her relationship with her husband was friendly and she replied with a long, trailing "Oh, yes" rather too loud for a plain affirmation. This overemphasis was the key that opened the door to the real situation. There was no doubt that she had to cover up something she did not care to divulge.

As to the children, she felt an "urge to leave them in the house" and go away, although she had never done it.

This time she cried and said that she often cried without any known reason.

The husband was invited to the doctor's office. He was a large, jovial man, who liked to enjoy life. He knew that she resented his being away evenings with friends. But she would be welcome if she only consented to accompany him. He

played cards at this or that friend's house or chatted. She, however, hated the games and small talk and was bored each time she did go with him. She sulked the entire evening.

He accused her of being too cranky and meticulous with the children—an overattentiveness which clinched with her unavowed desire to put as much distance as possible between her and her husband. But this flight into the exaggerated care of the children was also unsatisfactory, as she really ceased to be fond of them. Mental illness would have been a more logical escape. She was inclined toward it, but fortunately she did not go so far.

There was no need of a very deep analysis to find that the spectre of an old love, from the days of her early adolescence, had come back to haunt her dreams. It had been but a passing caprice and she had not met that boy again, nor did she know what had become of him. Consciously he was completely "wiped off her mind."

It was sufficient to reflect these inner thoughts of hers aloud, in order to make her smile and to cause her to treat them as highly ridiculous. This was the beginning of the end of her trouble.

Of course, both she and her husband had to reach a compromise whereby he would avoid neglecting her and she would accept some of his habits.

Now, in 1936, this woman is still well, nothing bad has occurred and the marital relations have not been disturbed.

"THIS PERPETUAL BELLY"

Emerson, in his essay, *Representative Men*, says "What can I do against the influence of race in my history? What can I do against hereditary and constitutional habits, against scrofula, lymph, impotence, against climate, against barbarism, in my country? I can reason down or deny everything, except this perpetual belly, feed he must and will and I cannot make him respectable."

A Latin student, when asked to make, at

sight, a free translation of *facilis descensus averni*, with a sudden burst of enthusiasm replied, "Going down hill is easy, the hell of it is to get back."

The accumulation of fat which results in any form of ptosis is easy, insidious, undermining, corroding and brings in its train conditions which are dangerous, so, as the Latin student said, It is Hades to get back—Prof W G Anderson, M D, Yale Univ

EDITORIALS

A Ubiquitous Lesson

The current politico-economic scene holds many lessons for self-styled liberals, in the profession and out, who have been playing with the idea of state medicine. The most extreme example is furnished by Russia, where, in fear of deviating in some minute detail from the party line, executives and engineers have abandoned all initiative and personal judgment, and industry is lapsing into a paralysis of indecision. Admittedly this is an extreme case, but in less critical times the members of a state bureaucracy are almost as easily intimidated by the threat of losing their political necks.

The Fascist states present a similar spectacle. In Germany scientific medicine is threatened by the "natural" therapy favored by some of the party leaders as well as by the racial discrimination which has terminated the careers of many brilliant clinicians and research workers.

It can't happen here? The industrial chaos prevailing in the Middle West shows how quickly impartial justice weakens before the partisanship of a strong administration.

All this may seem remote from medical practice, but from the long view it is entirely germane. Under state medi-

cine, the physician holds a subordinate position in a political bureaucracy. His methods are controlled by the theories and prejudices of his administrative superiors, who may be laymen without medical training or experience. His initiative is deadened by the burdensome clerical routine imposed upon him. His judgment is circumscribed by often foolish regulations. Fear of political consequences weakens his professional independence.

These dangers, ignored or brushed aside as negligible by the advocates of compulsory sickness insurance, are revealed in their true proportions by current happenings wherever the state has invaded the normal sphere of private enterprise and crushed the independent judgment and liberties of the individual. The suppression of petty rights is soon followed by the obliteration of important ones.

The moral is that the physician must resist any attempt, no matter how seemingly unimportant, to bring his profession under political control.

Medicine Cooperates

The opposition of organized medicine to political control does not mean that the

Events

THE SAMARITAN HOSPITAL in Troy honored its founding fathers on May 20 at the annual dinner of the Board of Directors, when tribute was paid Dr James P Marsh, one of the founders and a member of the staff since 1896, Dr Frederick A Smith, the second of the two living founders and original staff members, and Dr John B Harvie, member of the consulting staff since 1906. The guests of honor witnessed the unveiling of a portrait of the late Dr Everard D Ferguson, one of the five original staff physicians and a founder, which was presented the hospital and unveiled by his son, Smith F Ferguson of Philadelphia.

THE TENTH ANNIVERSARY of Trinity Hospital, in Brooklyn, was celebrated at a dinner at the Waldorf Astoria on June 24.

A TESTIMONIAL DINNER to Dr David Ginkgold, president of the medical board of the Beth Moses Hospital, in Brooklyn, was tendered on May 27 at the Hotel Towers by the medical staff.

THE ALUMNAE ASSOCIATION of Mercy Hospital, of Buffalo, held its annual spring supper dance at the Wanakali Country Club on May 22.

Newsy Notes

HALF OF THE TOTAL GROUP hospitalization enrollment for the entire country is to be found in New York State, declared Dr Claude W Munger, president of the American Hospital Association, at the hospital convention of New York State on May 20.

A PLEA FOR THE FREEDOM of "voluntary hospitals" from governmental control was made by Dr S S Goldwater, Commissioner of Hospitals, in the luncheon address at the thirteenth annual conference of the Hospital Association of New York State, at the Astor. "It is the function of government," he said, "to pay for all free work in voluntary hospitals, if," he added with emphasis, "you want to see the whole ideal of American democracy fail here and now."

"Irreplaceable losses in the relationship between patient and doctor" would follow, he said, if voluntary hospitals were government controlled, with the resultant tendency to institutionalism, centralization of the profession and mechanization of hospital service. Dr Goldwater concluded with praise of the Associated Hospital Service, five-cents-a-day group hospitalization plan, but said it must be extended to include persons in the lower income groups if it wished to be really successful.

THE UNITED HOSPITAL FUND has distributed a total of \$1,441,866.97 to member hospitals on the basis of free services rendered last year, it is revealed by Edwin P Maynard, vice-president of the fund.

Trustees of the organization voted grants that brought the entire amount to the present total. The funds distributed on May 25 amounted to \$728,390.19.

In addition a sum of \$275,000 has been set aside by the distributing committee for future allocation to hospitals for emergency needs.

Grants for medical social service work were also given to nine volunteer women's committees connected with municipal hospitals and seven Catholic hospitals also received money.

. . .

THE CHARGES AGAINST THE sit-down strikers in the Jewish Hospital in Brooklyn have been either dismissed or the strikers given suspended sentences, at the request of the hospital directors. The charges involved forcible entry, endangering patients' lives, committing a public nuisance, conspiracy to prevent nurses and interns from working, and unlawful assemblage. The hospital directors urged the court not to conduct any further prosecutions in the case because they felt many of the defendants had been led into their present predicament by outside organizers and agitators. It was a generous gesture on the part of the directors, remarks the Brooklyn *Eagle*, and indicated the lack of any desire merely to secure the punishment of offenders but rather to assure the future safety of patients. It will be hoped that hospital employees will take to heart their experiences and realize that they cannot seek to right their grievances—no matter how just they

to say anything about them? That is in brief the net finding of the committee, after taking tomes of testimony from the Ministry of Health, the various associations of local authorities and of their servants, also the Society of Medical Officers of Health, the Royal Medico-Psychological Association, and bodies representing architectural, structural engineering, gas and electricity, and other interests.

But fortunately it is equally British, if the Committee on Costs cannot find anything to say about costs, to try to produce some other information that will be of use.

So, as their report is digested in *The British Medical Journal*, the Committee "avoids cost figures as far as possible and discusses the respective advantages of different methods of planning and equipment."

Perhaps we can learn something from these recommendations, with due allowance for the different conditions here.

For example, they take up the "Ward unit" of the acute general hospital, by which they mean a self-contained unit under the charge of one sister, comprising about thirty beds in one or more wards with associated service rooms. The committee thinks that such a ward should include at least four one-bed rooms. As to whether the remaining twenty-six beds should be in one large ward or two or more smaller wards there is much to be said on both sides. The smaller wards offer greater privacy for the patients, provide opportunity for classification, limit the spread of infection, and facilitate periodical cleaning. The large ward is simple and economical to plan, easier to supervise by the nursing staff, and lends itself more readily as a rule to a good arrangement of window space. The committee is evidently impressed by the advantage of replacing the large ward by smaller wards. It recognizes that this plan may mean increased capital cost, though this need not be more than £4 or £5 per bed, and with a moderate degree of subdivision, such as the replacement of the main ward by two smaller wards, a plan might be devised which would entail no extra cost at all.

The space per bed is usually expressed in cubic feet, and this is also open to a fallacy because height is relatively unimportant in comparison with floor area and

distance between bed centers. With an adequate area to each bed and sufficient distance between adjacent beds the height can be determined by considerations of proportion and amenity. The Committee found general agreement among its witnesses that for convenience of nursing in acute medical and surgical wards a wall space of eight feet between bed centers is desirable.

As for the total width of the ward, having regard to the traffic along the central gangway, the London County Council has ordained twenty-six feet, the Ministry of Health in 1924 recommended twenty-four feet, which would leave ten feet for the gangway. The Committee's view is in favor of the greater width.

More precise figures are set out for the the operating theatre and ancillary rooms. It is considered that a good average provision of floor space for an operating theatre in a non-teaching hospital would be twenty-two feet by eighteen feet, for the anesthetizing room 140 square feet, and for the sterilizing room with hand-washing facilities for surgeons and nurses 230 square feet in a single suite and 300 square feet when there are two theatres and anesthetizing rooms with ancillary accommodation common to both. Stress is laid on the desirability of direct access from the anesthetizing room to the theatre and of exit from the theatre other than through the anesthetizing room.

It is considered that in an acute general hospital of, say, 400 beds, residential accommodation should be found for the medical superintendent and his deputy, five other medical officers, matron, sisters, and nurses to the number of 133, and maids to the number of twenty-four. A separate house should be provided for the medical superintendent and small houses or self-contained flats for one or more married medical officers. Without such separate accommodation outside the administration block it is considered that it would be difficult to retain the right type of man in the hospital medical service. The appropriate room accommodation for married officers is indicated. Other resident medical officers may be housed in the administration block, each medical officer to have a sitting-room and bedroom, and there should be a common dining-room with serving pantry.

Medicolegal

LORENZ J. BROSNAN, ESQ

Counsel, Medical Society of the State of New York

Hospitals—Responsibility for Injuries Sustained by Irrational Patients

A case came before the highest court of one of the States in the Middle West a short time ago, in which the problem presented was the circumstances under which a hospital might be held to liability for injuries self-inflicted by an irrational patient.*

The institution involved was operated as a general hospital in a large city and was conducted for the care and treatment of medical, surgical, obstetrical, and pediatric cases. It did not undertake to furnish medical or surgical treatment, but was a place where various doctors in the vicinity sent patients under their care. The hospital attendants furnished, performed the usual routine services and carried out the instructions of the attending physicians. No patient was furnished with a nurse in constant attendance unless under a special arrangement.

The patient who was plaintiff in the litigation, was brought to the hospital by his brother who requested admission of the patient, and informed the admitting clerk that the case was under the care of Dr. J. The brother left without stating the nature of the ailment and Dr. J. was notified. Dr. J. gave certain instructions for the patient's care which were recorded in the "doctor's order sheet" and included a prescription calling for sodium amytal and the direction that he should have strict bed rest with no visitors. No history of the case was taken by hospital attendants, and no information was given them by anyone concerning his illness, previous condition or actions. A notation on the record made by Dr. J. on the date of admission was as follows: "Patient seen in the office (Dr.'s office) moderate depression and quite restless, wanted to come to hospital. He had a similar spell one year ago."

The patient was first assigned to a ward room where he remained for three days and then he was transferred to a single room. That room had one window, the lower half of which was barred, and the upper pane of which could not be lowered.

The hospital records indicated that for

three days his condition was uneventful. On the day that he was transferred to the private room the nurses' notes contained the following entry: "A.M. 3 (18th Awake—talks very peculiarly—eyes have wild glare—restless—very depressed—seen by Dr. C (intern)." The nurse who made the entry had been sufficiently disturbed to call the night supervisor and the intern had given a sedative. On the same day before his transfer from the ward, an intern who saw him made the following comment which was noted in the chart: "Patient is a white male of stated age, well-developed, well-nourished, walking about. Appears to be much depressed, is very restless, is walking about ward. Asking for folks to be sent for and asking that they be told to pray for him. Seems to think he has done something wrong and wants to confess."

During the time the patient remained in the private room there were on that floor a graduate nurse, a supervisor, and four student nurses. One of them was in his room every thirty or forty minutes and probably more frequently. When Miss M., one of the nurses, went into his room she found him on one occasion sitting on the edge of the bed, his face in his hands. She asked him to lie down, and he did so without speaking. No restraint to confine him to his bed was attempted, however. Later one of the student nurses also found him sitting on the edge of the bed and at her request he got back into bed. At about four o'clock that same afternoon two nurses observed him to be quietly lying in bed. At 4:30 P.M., however, a loud noise was heard, and investigation showed that the patient had jumped out of the window, after first breaking the upper pane. The window was located on the third floor and although he sustained very serious injuries the patient survived. Later on when questioned by a specialist in mental and nervous diseases as to how he went out of the window the patient stated that it was "decided very quickly. It took him just a matter of a few moments to decide what to do."

The patient brought an action to recover damages for his injuries against the hospital. He charged in his complaint that the injuries were caused due to the hospital's negligence.

* Messedahl v. St. Luke's Hospital, 259 N. W.

may be—in the same manner that workers might in a steel mill. In the cases of hospitals the welfare of helpless patients is involved.

A DRIVE HAS BEEN LAUNCHED by the New York Chapter of the Interne Council of America for a \$1,000 annual salary for the 500 internes of the municipal hospitals.

Public hearing on a bill to this effect, introduced by Alderman James A. Burke, of Queens, was asked in telegrams sent to Alderman Walter Hart, of Brooklyn, chairman of the committee on local laws.

This was announced by Dr. Joel Hartley, chairman of the chapter, following a meeting of internes representing the 1,000 members of the council in both voluntary and city hospitals.

"Despite the high quality and indispensable character of their service," Dr. Hartley said, "the interns have been the lowest paid of the city's employes, having only recently been granted a \$15 monthly 'pin money' handout."

THE TROY HOSPITAL Alumnae Association held a Nursing Institute on May 26-27 at the hospital in charge of Miss Lillian M. Anslow, chairman of program. Demonstrations were given by the supervisors of newer nursing procedures, and lectures and discussions by the doctors on the newer drugs and treatments.

DR. S. S. GOLDWATER, Commissioner of Hospitals, announces the inauguration of an Institute for Teachers of Men and Women Hospital Attendants, to instruct nurses' aides in "doing the common task in an uncommon manner." It is believed by the Department that one result of the eight-hour day, which became legally effective on July 1, will be a more economical use of the services of fully trained nurses, and an increasing reliance upon the Attendant or Aide group—a group which, if carefully trained, can safely be entrusted with the performance of many bedside tasks. The

principal aim of the Institute is to explore effective methods of teaching for the Attendant class, already numerous in both municipal and private hospitals and destined to become more numerous with the passing of the years.

BENJAMIN TAYLOR, thirty-four years old, a patient at the Johns Hopkins Hospital, was killed and two operating-room attendants were injured when anesthetic gases exploded during an operation on June 1, according to a dispatch from Baltimore.

Mr. Taylor was undergoing an operation for a carbuncle on the neck. The operation was nearly completed, it was said, and an electric cautery machine was being used when suddenly there was an explosion of the gas in the patient's lungs, killing him instantly, hospital authorities said.

A nurse standing near the table and another who was administering the anesthetic were burned. Neither was seriously injured. The operating surgeon escaped injury.

Dr. Winford Smith, director of the hospital, said in a statement:

"The gases in mixture ordinarily are not explosive—oxygen, nitrous oxide and ether. We use them in conjunction with cautery thousands of times every year. It was just one of those unexplainable accidents that happen."

• • •

THE MEDICAL STAFF of Rome and Murphy Memorial Hospitals on May 25 notified the city that after May 31 its members no longer would serve hospitalized relief cases without compensation. This was the second ultimatum. April 6, the nineteen physicians advised the welfare department they wanted \$200 a year each for treatment of hospitalized relief clients. They set May 1 as the deadline. Corporation Counsel M. J. Larkin advised the city is required by law to take care of its needy sick and therefore the doctors can compel payment.

Declaring an emergency effective, City Health Officer L. N. Eames, M.D., called upon the aldermen to appropriate sufficient funds to pay physicians for care of hospitalized relief cases.

"Why in the world did you write a policy on a man 98 years old?" asked the indignant insurance inspector.

"Well," explained the new agent, "I

looked in the census report and found that there were only a few people of that age who die each year."

—Colorado Medicine

Across the Desk

Bad Times, Good Health, Good Times, Bad Health

Considerable surprise has been expressed, during the business slump, at the continued good health of the people and the low death rate. The depression has been compared to a war, a famine, a visitation of the plague, or some other such calamity, and many have apparently expected disease and death to play havoc among the unemployed and those on reduced income.

Nothing of the kind has happened, and as we emerge from the depression period some explanation seems called for. In probing for the cause, a California physician with an analytical mind, Dr. Emil Bogen of Olive View, has made the intriguing discovery that the health of the people, over a long period of years, has always been better in bad times and worse in good times.

The clearest and most accurate index of the general health of the people is the death rate, and the mortality figures are readily obtainable and easily charted, says Dr. Bogen in a paper read before the Southern California Medical Association, and now published in *California and Western Medicine*. When this is done, the chart of the rise and fall of the death rate can be superimposed upon a chart of the rise and fall of prosperity, and we see before our eyes the death rate going up when prosperity goes up, and going down when prosperity falls! As Dr. Bogen puts it, "the fatal cost of business prosperity becomes evident, and the life-saving value of a cessation of commercial activity is revealed." The most casual inspection of the figures shows sharp drops in mortality rates following the beginning of economic declines, and actual rises in periods of business booms.

Mysterious Causation Seems at Work

And it is not only in this country that this strange game of follow-my-leader is found. In England and Wales and, indeed, wherever figures are available in modern industrialized communities, not only for the recent depression, but for all the commercial cycles of the past century, the death rate goes down instead of up in hard times.

Some may say that the death rate rises in prosperous times because people overeat, and

falls in bad times because they eat less, but this reasoning proves fallacious when we examine the figures, say, for tuberculosis, a disease closely related to diet. Undernutrition favors its development and an increase in the diet reduces the mortality.

Fortunately for the purposes of this investigation, the tuberculosis death rate is available for large American cities like New York, Boston, and Philadelphia for more than 120 years. Analysis of the curve of mortality from tuberculosis, covering nearly the entire life of our industrial civilization, shows as clear as daylight that tuberculosis rises in prosperous times and falls as business falls.

Some mysterious causation seems to be in operation here, by which the Grim Reaper speeds up as the factory wheels begin to whirl, and slackens the swing of his scythe as they subside into silence. Perhaps we use more alcohol and indulge in more dissipation in the days and nights of prosperity. Perhaps the increase in traffic and personal contacts, with greater chances of infection, the nervous strain of boom times, the greater physical and mental exertion, may have something to do with it. Perhaps the rest from labor during depression periods decreases the death rate, and perhaps the tuberculous and others in poor health and strength are the first to be laid off when the slump comes and the last to be re-employed when it ends, so that the compulsory rest may go first to the very ones who need it most.

Food is Scarcer When Times are Better

Another reason, however, occurs to the mind of our California investigator. He points to something that every consumer has sadly noticed, the sharply rising prices of food that accompany the return of good times. The housewife must lay out her money more carefully and the market-basket comes home with less in it. In plain English, Dr. Bogen tells us despite the almost universal popular belief to the contrary, people eat more in times of depression and therefore, are healthier, and eat less in times of commercial prosperity, and therefore die of

in caring for him while he was mentally deranged, delirious, and not in possession of his mental faculties. Knowledge on the part of the hospital of these conditions was specifically alleged in the plaintiff's complaint.

The facts as developed by the evidence on the trial were substantially as outlined above. There was testimony by plaintiff's expert that he had been suffering from "manic depressive insanity." There was testimony by plaintiff's relatives that before entering the hospital he had talked about intentions of suicide. However there was no proof that any such information had been given the hospital before the man had jumped from the window, nor was there any evidence that his physician had left any special instructions as to constant care or restraint.

The case was submitted to the jury and the result was a judgment in favor of the plaintiff in the sum of \$16,000. An appeal was taken on behalf of the hospital to the highest court in the state, the contention urged upon the appeal being that taking all the evidence viewed in a light most favorable to the plaintiff, there was no support for a finding of negligence, and hence of liability on the part of the defendant.

The appellate court ruled that the defendant's contention was correct and reversed the judgment of the trial court and directed judgment for the hospital. In its opinion the court said:

Certainly, when experienced doctors in charge of the case, with knowledge of all that had occurred did not consider restraints necessary, it was not for the interns or nurses to take it upon themselves to apply restraints upon a patient who had not displayed a proneness to do himself or anyone else injury. It is conceivable that application of restraints upon the person of one who is already nervous may induce an overwhelming desire to fight against the bonds, thereby doing himself more harm than good. The advisability of applying restraints should rest in the discretion of the attending physician. With respect to the duty of hospital attendants to obey instructions of the physician in charge of the patient, it is stated in *Byrd v. Marion General Hospital*, 162 S. E. 738, 740: "The great weight of authority, however, establishes the principle that nurses, in the discharge of their duties, must obey and diligently execute the orders of the

physician or surgeon in charge of the patient unless, of course, such order was so obviously negligent as to lead any reasonable person to anticipate that substantial injury would result to the patient from the execution of such order or performance of such direction. Certainly, if a physician or surgeon should order a nurse to stick fire to a patient, no nurse would be protected from liability for damages for undertaking to carry out the orders of the physician. The law contemplates that the physician is solely responsible for the diagnosis and treatment of his patient. Nurses are not supposed to be experts in the technic of diagnosis or the mechanics of treatment."

We do not agree with respondent that the employees of defendant in the exercise of reasonable care should have ascertained plaintiff's condition previous to his entry to the hospital. To do so would have required interviewing relatives. Plaintiff was left at the hospital by his brother without a word of information as to his ailment. The instructions received from his doctor indicated nothing more than that plaintiff was in need of rest. He was under Dr. J's care, who presumably was aware of his patient's condition. Dr. J was not an employee of the defendant, as far as the record shows. His negligence, if any there was, cannot be imputed to defendant. If defendant was a hospital maintained and operated for the purpose of treating and curing diseases, physical and mental, and having its own staff of doctors and specialists for that purpose, it probably would be its duty to ascertain all it could concerning an external patient's previous history, especially so with respect to hospitals specializing in the cure of mental disorders. In the instant case, plaintiff's relatives must be charged with knowing the nature of the services rendered by defendant, that no one would be in constant attendance, that defendant did not specialize in mental cases generally and knew nothing of plaintiff's case, particularly. It would be a harsh rule indeed that would charge the authorities of a general hospital to go in search of the relatives of every patient entering it under the care of a physician of his own or his relatives selection, and ascertain independently of the attending physician, the nature of the patient's ailment and then to exercise their own judgment as to treatment required.

It is important to note that the appellate court in deciding this appeal, decided it entirely apart from the general rule in this State that in most instances a hospital operated as a charitable institution may not be held responsible in damages for the acts of its doctors, nurses, interns, and attendants.

Much so-called "research" is a mere beating of air, a form of solemn trifling, wasteful alike of time and money.—*The British Medical Journal*

Patients in the older age groups do not necessarily present greater surgical risks than those in the younger age groups.—*Staff Meetings of Mayo Clinic*

Across the Desk

Bad Times, Good Health, Good Times, Bad Health

Considerable surprise has been expressed, during the business slump, at the continued good health of the people and the low death rate. The depression has been compared to a war, a famine, a visitation of the plague, or some other such calamity, and many have apparently expected disease and death to play havoc among the unemployed and those on reduced income.

Nothing of the kind has happened, and as we emerge from the depression period some explanation seems called for. In probing for the cause, a California physician with an analytical mind, Dr Emil Bogen of Olive View, has made the intriguing discovery that the health of the people, over a long period of years, has always been better in bad times and worse in good times.

The clearest and most accurate index of the general health of the people is the death rate, and the mortality figures are readily obtainable and easily charted, says Dr Bogen in a paper read before the Southern California Medical Association, and now published in *California and Western Medicine*. When this is done, the chart of the rise and fall of the death rate can be superimposed upon a chart of the rise and fall of prosperity, and we see before our eyes the death rate going up when prosperity goes up, and going down when prosperity falls! As Dr Bogen puts it, "the fatal cost of business prosperity becomes evident, and the life-saving value of a cessation of commercial activity is revealed." The most casual inspection of the figures shows sharp drops in mortality rates following the beginning of economic declines, and actual rises in periods of business booms.

Mysterious Causation Seems at Work

And it is not only in this country that this strange game of follow-my-leader is found. In England and Wales and, indeed, wherever figures are available in modern industrialized communities, not only for the recent depression, but for all the commercial cycles of the past century, the death rate goes down instead of up in hard times.

Some may say that the death rate rises in prosperous times because people overeat, and

falls in bad times because they eat less, but this reasoning proves fallacious when we examine the figures, say, for tuberculosis, a disease closely related to diet. Undernutrition favors its development and an increase in the diet reduces the mortality.

Fortunately for the purposes of this investigation, the tuberculosis death rate is available for large American cities like New York, Boston, and Philadelphia for more than 120 years. Analysis of the curve of mortality from tuberculosis, covering nearly the entire life of our industrial civilization, shows as clear as daylight that tuberculosis rises in prosperous times and falls as business falls.

Some mysterious causation seems to be in operation here, by which the Grim Reaper speeds up as the factory wheels begin to whirl, and slackens the swing of his scythe as they subside into silence. Perhaps we use more alcohol and indulge in more dissipation in the days and nights of prosperity. Perhaps the increase in traffic and personal contacts, with greater chances of infection, the nervous strain of boom times, the greater physical and mental exertion, may have something to do with it. Perhaps the rest from labor during depression periods decreases the death rate, and perhaps the tuberculous and others in poor health and strength are the first to be laid off when the slump comes and the last to be re-employed when it ends, so that the compulsory rest may go first to the very ones who need it most.

Food is Scarcer When Times are Better

Another reason, however, occurs to the mind of our California investigator. He points to something that every consumer has sadly noticed, the sharply rising prices of food that accompany the return of good times. The housewife must lay out her money more carefully and the market-basket comes home with less in it. In plain English, Dr Bogen tells us despite the almost universal popular belief to the contrary, people eat more in times of depression and, therefore, are healthier, and eat less in times of commercial prosperity, and therefore die of

CHART I—THE DEATH RATE AND BUSINESS
CYCLE

CHART II—PHTHISIS AND PROSPERITY

tuberculosis and other diseases of under-nutrition in what we call the good times. True, this seems so paradoxical as to be preposterous, and Dr Bogen, realizing that fact, rallies two striking pieces of evidence to the defense of his argument. First, take the figures for diabetes, traditionally associated with overeating. Diabetes, curiously enough, decreases in periods of prosperity and increases in times of business depression. If diabetes has any relation to diet, this suggests that people eat more in hard times and less in prosperous times.

Which leads our California investigator to his next piece of evidence—the per capita consumption of meat, as given in the *World Almanac*. We might naturally think that folks eat more meat in the prosperous years, but the cold figures show just the opposite—during prosperity, meat consumption tends to decline, during depressions it tends to rise.

More Money Buys Less

There can be no doubt whatever that the worker gets more pay in good times than in bad, but does his money buy as much? The index number of the purchasing power of the wages of union labor, as measured in terms of food, is available for the past two decades, and here also, we are told, the food value of union wages has run contrary to the death rate and to the curves of prosperity. The worker has had more money in good times, but it has bought less. The worker's nutrition is better when times are worse!

At any rate, we know that efforts to show

that the unemployed and their families have had poorer health during the depression have had no success at all. The unemployed frequently turn their energies to gardening, raising chickens and keeping pigs and cows, and their families revel in a diet of fresh vegetables, fried chicken, pork chops, rich milk and ice cream instead of provisions from the grocery shelves. Investigations of the health of school children have shown that their health was better, rather than worse, during slump periods.

The growls of certain social workers who predict dire results of our present social and medical system in a morbid undertone should now cease, Dr Bogen remarks. The terrible ravages of disease and death among the unemployed are non-existent. There is nothing to it. Of course this does not mean at all that funds and efforts spent on public health and social service should halt or even be lessened, but, at least, do not try to saddle any illness that exists on the hard times. Rather, we should realize that danger looms with the return of prosperity, that as prices rise out of proportion to the buying power of the masses, malnutrition and disease may be expected, and we should prepare to meet it. Our plans should be so made and carried out, thinks Dr Bogen, that energies expended to improve the health of the people should not take the form of emergency measures, to tide us over a temporary depression, but should rather be directed at the real dangers to health and life that lurk in the blaze and heat of the coming economic revival.

HOW MANY NEED HELP?

Within a small margin of error, about fifty per cent of the population goes through the year without any illness. Fifty per cent of the illnesses of the other half are not disabling. One-half of the remainder, or about 12½ per cent, are of a minor character, such as the common cold, and involve a disability of less than a week. This leaves about 12½ per cent who have serious illness and an expense for wage loss and for medical care sufficient, to constitute a real problem. Of these, many are able to meet the necessary expense from their own savings, by deferred payments or

from regular income, just as they meet other extraordinary expenses. Thus it seems reasonable to assume that five per cent—certainly less than ten per cent—of the total population are unable to meet their sickness expense without great sacrifice. This is still enough of a problem always deeply to concern organized medicine.

It is a testimony to the accuracy of these figures that when county medical societies have set up machinery to provide service for those otherwise unable to obtain it the number served has almost invariably been between three and five per cent of the total population.—J A M A

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

REVIEWED

Nostrums and Quackery and Pseudo-Medicine. By Arthur J Cramp, M D Volume III Octavo of 242 pages, illustrated Chicago, American Medical Association, 1936 Cloth, \$1 50

This volume includes many patent medicines and proprietary remedies not covered in the two previous volumes. Analyses of many of the older preparations are brought up to date. This book is indispensable to any

physician who desires to know the composition of the innumerable secret preparations advertised to the laity. It also exposes the fraudulent and extravagant claims made for these products by their manufacturers. The medical profession owes a debt of gratitude to Dr Arthur J Cramp who until recently was Director of the Bureau of Investigation of the American Medical Association.

CHARLES SOLOMON

ORDERING BOOKS

As a service exclusive to our readers books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W 42nd St., N Y C.) postage prepaid. Order must be accompanied by remittance covering published price.

Rural Health Practice By Harry S. Mustard, M.D. Octavo of 603 pages, illustrated. New York, The Commonwealth Fund, 1936. Cloth, \$4.00

This book, as its name implies, is of interest primarily to health officers in rural areas. On the other hand, as technical procedures of public health work in their fundamentals are the same for municipalities and suburban or rural districts, the book may be read with profit by physicians wherever located. It is in the administrative phases that the subject matter largely deals with rural problems, therefore, the book is recommended particularly to members of the medical profession who practice in the rural and small town areas. As the work of any physician practicing modern medicine brings him into direct or indirect relations with public health activities every day, it is desirable that he keep informed on matters such as are discussed in this volume.

ALFRED E. SHIPLEY

The Diagnosis and Treatment of Diseases of the Liver and Biliary Tract By John Phillips, M.D. Revised by Russell L. Haden, M.D. (Reprinted from *Oxford Monographs on Diagnosis and Treatment* Octavo of 539 pages, illustrated. New York, Oxford University Press, 1936. Cloth, \$7.50)

This is an excellent book. It covers the field of anatomy, physiology and diseases of the liver and biliary tract in a comprehensive manner. Liver function tests are described and evaluated for the clinician.

The clinical presentation of liver and biliary tract disorders is concise and up to date. The text is easy to read and to understand.

Treatment is discussed in an orderly and practical manner.

The bibliography is complete. This book will be of value to students as well as to those interested in general medicine.

EUGENE R. MARZULLO

Medical Morals and Manners By Hubert A. Royster, M.D. Octavo of 333 pages. North Carolina, University of North Carolina Press, 1937. Cloth, \$2.50

Dr. Royster has collected his papers and addresses of the past forty years and now offers them in book form. They are in the Oslerian tradition, though distinctive in thought and style. Although delivered or published at various periods, they "hang together" remarkably well, and by that we do not just mean that the medical common denominator is what binds the matrix, apart from that, the implications are interrelated. While much of the subject matter has to do with surgery, a good deal of other ground is covered. Dr. Royster even (courageously)

writes a chapter on Women and the Doctor which combines shrewd interpretation and a degree of naïveté—something we fancy is almost inevitable when a mere man undertakes to discuss such a formidable and intricate topic. Mencken set a mark in his *In Defense of Women* which other men can hardly hope to approach—an achievement probably due to his feminine type of mind.

There are some unusual thumbnail sketches of country and small town practitioners of superior order at the end of the book—like the one about Budd of Chatham. Said Budd: "I was driving along the road late one summer afternoon, half asleep, with the reins between my knees, when a young fellow hailed me 'Doc,' he said, 'I wish you would lance this risin' on my leg for me.' Without examining it, I took out my thumb lancet, told him to put his foot upon the buggy wheel, and stuck the blade deep into a large swelling in his popliteal space. I give you my word the blood spurted four feet high. Realizing that I had opened the sac of an aneurism, I told him to grab it tight, and quickly tore up my linen lap robe and made a Spanish windlass. Applying this above the knee, I controlled the bleeding. I took him home, and that night I tied his femoral artery and, do you know, that d—n fool got well!" The same Budd got a voluntarily bed-ridden woman out of her long-occupied couch by undressing as if to share the bed with the maiden lady of uncertain age—result as the doctor climbed in at one side, the patient, who had not walked or left her bed in a year or more, got out at the other side and ran out of the house some distance down the road.

ARTHUR C. JACOBSON

Maternity and Post-Operative Exercises By Margaret Morris, C.S.M.M.G. Octavo of 152 pages, illustrated. New York, Oxford University Press, 1936. Cloth, \$2.00

This is a book of exercises intended for midwives, masseuses and nurses who have taken the "Maternity and Post-operative Exercises Diploma of the International Institute of Margaret Morris Movement." It is not suitable for physicians, yet interesting. Systematized exercises associated with proper breathing and timing to a slow steady rhythm are recommended after operations and delivery, including the first and second stages. Phonograph records for some of these exercises are available,—Schubert's music, slow tango tunes or drum rhythm. Professors Johnstone and Fraser have given their approval in separate introductions,—and Johnstone particularly has had experience with the system in his hospital. Though these exercises may

seem impracticable, it is quite possible that they may be very useful to bring about mental relaxation in the patient, and so lessen her fear of delivery

CHARLES A GORDON

Juvenile Paresis By William C Menninger, M D (The Menninger Clinic Monograph Series No 1) Octavo of 199 pages, illustrated Baltimore, The Williams & Wilkins Company, 1936 Cloth, \$3 00

The author has written a monograph on the subject of juvenile paresis, basing his report upon 43 cases of juvenile parietic neurosyphilis personally observed and 610 cases recorded in the literature

Juvenile paresis represents less than 2 per cent of all the cases of parietic neurosyphilis and 1 per cent of congenital syphilis The average age of onset is about 13 years In the families of the 653 cases, 56 5 per cent had some member with either clinical or serological evidence of syphilis In 55 instances there was mental disease present in one or more non-syphilitic members of the family Sixty per cent of the juvenile parietics were normal mentally prior to the onset of the disease In 75 per cent there were stigmata of congenital syphilis present

The results of treatment of this disease have been markedly disappointing More success has been attained in those who had a normal period of development prior to the onset of symptomology Best results were obtained through the use of diathermy, arsenicals and heavy metals Malarial treatment with the use of trypanamide has also yielded some good results

There is an excellent bibliography The book shows evidence of having been carefully prepared The author is conservative in his conclusions It should be of marked interest to the profession.

STANLEY S LAMM

The Harvey Lectures Delivered under the Auspices of The Harvey Society of New York, 1935-36 Series XXXI Octavo of 255 pages, illustrated Baltimore, The Williams & Wilkins Company, 1936 Cloth, \$4 00

The contents of the 1935-1936 volume of Harvey Lectures consist of

Proteins and Proteolytic Enzymes, Dr Max Bergmann

The Significance of Chimpanzee-Culture for Biological Research, Prof Robert M Yerkes

The Virus Tumors and the Tumor Problem, Dr Peyton Rous

Relations between the Parathyroids, the Hypophysis and the Pancreas, Dr B A Houssay

The Interrelation of Cerebrum and Cerebellum in the Regulation of Somatic and Autonomic Functions, Dr John Farquhar Fulton

The Influenzas of Swine and Man, Dr Richard E Shope

Malignant Cells, Dr Warren H Lewis

The Physiology of the Bronchial Vascular System, Dr I de Burgh Daly

Needless to say, the latest thought on these subjects is expressed This little volume deserves a place of its own, in every medical library

MAX LEDERER

Here's to Crime By Courtney Ryley Cooper Octavo of 454 pages Boston, Little, Brown & Company, 1937 Cloth, \$2 75

In describing the extent and ramifications of criminology, the author questions the fitness of the expression, "Crime does not pay," inasmuch as it has come to constitute one of the nation's biggest businesses A book of this type has, of course, a more general appeal, although medical men will find a special interest in the various chapters devoted to prostitution, venereal diseases and drug addictions No attempt has been made to correlate criminology with the incidence of venereal diseases, but the close association of prostitution and crime is apparent The story that the author introduces, exposing the disgustingly small practices of the genito-urinary outcast, has the same sinister significance to ethical practitioners as have the derelictions of some petty dishonest official to the generality of honest crime investigators

We feel that the subject of criminology and, especially the premise of the organization of the criminal class, is worthy of a dignified presentation, even if a popular reportorial appeal is intended We fail to see the stimulation of interest in such chapter headings as, Hussies in Hiding, Ladies in Parlor A, A Shot in the Arm, Good Morning, Judge There is much that is disturbing and disheartening to be read here by the neophyte in the study of crime, but the real student must find a more lasting method of crime prevention than by beating sex tom toms and clanging corruption cymbals

JOSEPH RAPHAEL

Contraception as a Therapeutic Measure. By Bessie L Moses, M D Duodecimo of 106 pages Baltimore, The Williams & Wilkins Company, 1936 Cloth, \$1 00

This small volume is a report of the work done at the Bureau for Contraceptive Advice in Baltimore

The Bureau was the result of informal discussions among a small group of men in the School of Medicine and Hygiene

of the Johns Hopkins University, among whom the late John Whitridge Williams was the leader. It was felt that the time had arrived when the practice of contraception, as practiced by the general population, should be given a more precise and scientific investigation than had come from the activities of the usual birth control clinic.

For this reason, the Bureau was set up to run for a period of five years. It was opened on November 2, 1927, ran for five years and then closed. Only those patients were received who had been referred by a physician, and in the five year period, 1152 cases were observed and carefully analyzed.

The Bureau was in charge of Dr. Bessie L. Moses, who is a trained obstetrician, and a careful scientific observer.

The facts set forth in this report may be relied upon, and they are of great interest to those interested in the growing subject of contraception.

WILLIAM S. SMITH

The Practice of Medicine By Jonathan C. Meakins, M.D. Quarto of 1343 pages, illustrated. St. Louis, The C. V. Mosby Company, 1936. Cloth, \$10.00.

This interesting book is novel in its physiological approach to diseases of the several systems, in its inclusion of hundreds of appropriate illustrations, and in the fact of almost exclusive authorship by one clinician.

Chapters on Metabolism, the Urinary System, and the Nervous System have been contributed by Doctors Mason, Scriver, and Norman Petersen respectively. The rest of the 1,300 pages is from the pen of the well-known Professor of Medicine at McGill University and Physician-in-Chief to the Royal Victoria Hospital. It is a matter of amazement and wonder that such a volume could issue from the experience of one internist.

Broad handling of each subject characterizes the volume and the author never hesitates to question or shelve an hypothesis, etiological or therapeutic. His rich physiological experience dominates the book, and his discussions constitute a refreshing and valuable part of the text.

The illustrations, 505 in number, are a splendid feature, presenting definite pathological and clinical pictures. They have been chosen with rare judgment and are truly illustrative, not exhibiting, as in some other books, the greatest edema, the largest caput medusae, the most marked cardiac hypertrophy, etc., but showing the usual average bedside findings. They, therefore, are

most helpful to the student and practitioner. Nordenson's eight colored plates of studies of sternal marrow (puncture) are beautiful and informative.

The volume was issued too soon to include discussion of chemotherapy in pneumonia and streptococcal infections (sulfanilamid, etc.) The author's comments on specific therapy, however, are sufficiently pointed to put us on our guard concerning excessive claims for any one product, and he emphasizes that the two principal means of combatting pneumococcal toxemia and threatening anoxemia are the early use of antipneumococcal serum and oxygen therapy.

Therapeutics throughout is on a very sound basis.

FRANK BETHEL CROSS

The Principles of Bacteriology and Immunity By W. W. C. Topley, M.D. & G. S. Wilson, M.D. Second edition. Quarto of 1645 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$12.00.

Seven years after the first edition of this well known textbook a new edition has now been published which gives an impressive account of the tremendous progress in Bacteriology made during that period. In the preface to their first edition the authors designate their work as a textbook for post-graduate students. There is no doubt that the second edition fully serves that purpose but it is much more. It is indispensable for the specialist in Bacteriology and Immunity. The work does not only contain an almost complete review of the literature but also a critical discussion of those problems which are not yet definitely solved, and many valuable suggestions to their solution. It is much more comprehensive than the usual textbooks of bacteriology and more integrating than the excellent works which have been written by a variety of authors. It is almost unbelievable that this vast subject has been mastered by two authors only.

The book is divided into four parts, i.e. General Bacteriology, Systemic Bacteriology, Infection and Resistance, The Application of Bacteriology to Medicine and Hygiene. The first part comprises the important subjects of metabolism, antigenic structure, variation, bacteriophage. The overwhelming number of new facts is critically reviewed and their significance adjudged.

In the second part a gigantic attempt has been made to classify bacteria on the basis of their chemical properties, their behavior in the animal body and their antigenic structure. The subject of filtrable viruses is presented in a brief but exhaustive account.

The last part deals with the pathogenesis

of infectious diseases, their epidemiology, diagnosis, prophylaxis and treatment

Each of the four parts reveals the familiarity of the authors with the subject on the basis of their experimental experience. As a whole, the work of Topley and Wilson is a textbook of an unique, high standard

ULRICH FRIEDEMANN

International Clinics A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, etc Edited by Louis Hamman, M.D. Volume 3, 46th Series, 1936 Octavo of 339 pages, illustrated Philadelphia, J B Lippincott Company, 1936 Cloth, \$3 00

This volume, as other volumes of the Clinics, contains many valuable and pertinent papers. In surgery the presentations of malignant melanoma and of subdeltoid bursitis (acute) are of interest. In medicine an instructive paper discusses Hodgkin's disease, lymphosarcoma and aleukemic lymphadenosis. Undulant fever, angina pectoris, bronchial asthma, and nonorganic fatigue in the child are presented instructively. There is, in a neurological-pathological conference, the discussion of a case of carcinoma of the nasopharynx which is well worth studying. This volume contains so much of value that its study will well repay for the time spent

HENRY M MOSFES

Facts and Phagocytes The Story of the Development of Hydrochloric Acid Therapy By Burr Ferguson, M.D. Octavo of 270 pages, illustrated Youngstown, Medical Success Press, 1936 Cloth, \$5 00

This book presents some clinical facts on the stimulation of the white blood cells by hydrochloric acid. The author gives credit to those contemporaries who have used hydrochloric acid with success, and who have expounded theories on phagocytosis

Were this book written in an impersonal manner it no doubt would assume a place of authority as regards the use of hydrochloric acid both orally and parenterally. Unfortunately the author spends too much space to expound his personal grievances against the constituted authorities of organized medicine and seems to have no patience with criticism. This leads him to present the book more in a form of a faddist, than as a scientific contribution

There have been many books written and theories accepted, many have remained in use, but even those that have been discarded have left their authors a decided place in medical literature.

The reviewer suggests that the next edition of "Facts and Phagocytes" be revised omitting all personal references and using a narrative style as against the style suggestive of propaganda

MORRIS ANT

Applied Dietetics The Planning and Teaching of Normal and Therapeutic Diets By Frances Stern Quarto of 263 pages, illustrated Baltimore, The Williams & Wilkins Company, 1936 Cloth, \$3 50

This practical work on dietetics will meet the needs not only of the well-trained dietitian but also of the physician, whether he be general practitioner or specialist in the field. Frances Stern has long since established a reputation through her efforts to bring dietetics to the level of understanding of the patient. She has studied the dietary peculiarities of the Armenian, Italian, and foreign Jew with the same zeal which she applies to the American. In her *Applied Dietetics* she has crystallized her vast experience in the food clinic of the Boston Dispensary, and this in conveniently tabulated form so that the physician in need can grasp as he runs, rather than be obliged to wade through endless academic bulk

Applied Dietetics covers in terse style the principles of nutrition involved in the planning of normal and therapeutic diets, environmental factors which influence diet, means and methods of "putting it over" to the patient (whatever be his mental status), tables and charts to facilitate computation and construction of diets, dietary outlines to show wherein the normal diet is modified to meet therapeutic indications, and finally, typical diets and menus of all sorts. The doctor of medicine will find in this book a valuable adjunct to his therapeutic armamentarium

GEORGE E ANDERSON

An Introduction to Pharmacology and Therapeutics By J A Gunn, M.D. Fifth edition 16mo of 240 pages New York, Oxford University Press, 1936 Cloth

The fifth edition of Professor Gunn's book was made to conform to the 1932 British Pharmacopoeia and the 1936 United States Pharmacopoeia. In spite of the fact that the author prepared this short work on pharmacology for the medical student, the subject is adequately covered and does meet the needs of the practicing physician

This book is heartily recommended as an authoritative and concise treatment of the subject.

SOME NOTES ON POISONING BY *CLITOCYBE DEALBATA* (SOW) *VAR SUDORIFICA* (PECK)

SMITH ELY JELLIFFE, M D, *New York City*

Being "hoist by one's own petard" affords the stimulus for the present note. It also offers some evidence on a type of poisoning by a not uncommon species of fungus, the *Clitocybe dealbata* (Sow) *var sudorifica* (Peck), which Ford and Sherrick thought should have a specific name *Clitocybe sudorifica* (Peck) since *Clitocybe dealbata* (Sow) has been eaten apparently with impunity by many. Murrill in 1915 reports having examined the variety closely and claims it cannot be distinguished morphologically from *Clitocybe dealbata*. In view of a pronounced pharmacodynamic action, careful revision of the morphology of this variety (?) should be undertaken.

As an amateur mycologist for years, supposed to know his fungi, as well as his onions, to have had an experience of poisoning is amusing and profitable.

The season (1936) at camp on Lake George was exceptionally dry in June, July, and August. There were no fungi of any significance. My usual gatherings of *Russula virescens* and *Russula heterophylla* were absent and the numerous edible and enjoyable *Boletus* were conspicuous by their absence. *Agaricus (Psalliota) campestris* from the market, however were freely enjoyed save when the price climbed to seventy-five to ninety cents a pound. This was too much even for a Brillat-Savarin astronomer.

Even *Marasmius oreades* (fairy ring) was absent on the golf course near my camp. For many years it had been a steady stand-by during the summer for

soups, hashes, etc. In late September and October there was a little rain and the market had shut down on *A. campestris* and so, to the golf links! Here *Marasmius oreades* was semi-abundant but among them and growing in the same rings or in fairy ring like rings was another white spored fungus, which as a botanist I knew was not *M. oreades*, but it was so very similar I thought I would take a chance. I did not look it up in my library until later, but will mention certain differences at this time. It was, as stated, very similar to the fairy ring, but was a little more fragile, and a bit more moist. One of the features of *M. oreades* which I had grown to recognize even almost with closed eyes was its tendency to cling to the earth and pull up a bit of soil as one plucked it not breaking the rather tough stem. This *Clitocybe* only half clung to the soil and the stem was a bit shorter, larger, and less tough. The caps were very similar. Identical in color, in many specimens, especially the older ones, but younger and fresher specimens were a trifle whiter than *M. oreades*. The umbrella flared in typical *oreades* fashion, but the slight tawny umbonate mount of *oreades*, so well drawn in Gibson's work, was not there. The pileus was flatter. A few specimens on drying almost had the umbonate rise of *M. oreades*. These resemblances are here emphasized, for only a botanist or acute observer could separate the two species, especially when they were growing in the same ring side by side and intermingled.

We, a friend and myself, gathered about two cups of the mixed species and when I returned home I forgot to tell my maid to sort the more distinctly doubtful ones from the evident *M. oreades*. She also had gathered *M. oreades* before and knew them.

Two or three days later I had some excellent oyster stew with at least twenty-three specimens of my mixed collection. I was alone and forgot all about my intentions and doubts. Some cold salmon and vegetables followed and desert. This was at 5 P M my usual dining time, after a breakfast at 7 A M and no lunch. It was showery and beginning to be cold, the thermometer about 34-35° F.

Next day about noon (19 hours after eating) I noticed that the outside cold, wet weather was distinctly uncomfortable. I was chilly and hugged the kitchen stove a bit. As I had had a mild bronchitis with some small bronchopneumonic patches about three weeks previously and was just feeling better, although my vasomotors were unstable I at first thought maybe I had a recrudescence of my peribronchial infection. My forehead first, then arms and chest began to be moist and in about fifteen to twenty minutes they were wringing wet. This grew worse and worse and I was certain I was in for a pneumonia, or something, when I suddenly said to myself—"Mushrooms." I then asked the maid if she was all right and she reminded me that she had been invited out to dinner the night before and had not eaten any oyster stew. So I was sure it was mushrooms and then rehearsed my doubts as to the ones we had gathered mingled with *M. oreades*.

The perspiration spread, and was so heavy I was forced to change my underclothing (see account W G Smith). There was no salivation, no rhinorrhea, no diarrhea, no increase in urination, and no trace of gastrointestinal disturbance. My pulse had not changed, if anything it was a bit slower and steadier than usual, sixty-four. Apparently there were no blood pressure changes to palpitation. I had no blood pressure instrument at hand, and the nearest was fifteen miles away. Pupils were equal and unmodified and apart from the sweating and at first slight anxiety of this strange phenomena I noted no other sign. After about two

and a half or three hours I took ten m Tr belladonna, and ten to fifteen minutes later took ten m more. After about ten minutes or so there was a cessation of the sweating and of the repugnance to going into the cold damp air and "Richard was himself again." There were no after symptoms observed. Pulse went to sixty-eight—seventy-two but there was a slight increase in my activity. I had been sitting quietly by the stove for fifteen minutes. I had also tried to take a nap, but the sweating had been too abundant for comfort and the anxiety was appreciable for I recalled that muscarine poisoning often came on late and that its effects might be very protracted and serious.

The sweating was similar to that experienced following a good dose of Dover's powder without the quieting effect of the opium, or followed next day by a cathartic action which a dose of Dover's powder often accomplishes. I have never taken pilocarpine so I cannot compare the action.

Next day my botanical curiosity was rearoused and I sent specimens to the State Museum at Albany, after which I went through my herbarium and mycological literature I had kept and somewhat added to since young manhood.

Dr House at the Albany State Museum reported that my specimens corresponded with Peck's *Clitocybe sudorifica*. "The dried specimens received with your letter of the 30th of October, 1936, agree in general appearance and in spore character with herbarium material of *Clitocybe sudorifica*." But as is well-known partly dried fungi are hard to identify.

From the books of Gibson, Atkinson, Rieger, Cooke, Peck, and others I learned of *Clitocybe dealbata* var. *sudorifica* and fortunately having a fairly full set of Peck's reports, read of its action from specimens gathered in 1911 at Saratoga Springs some sixty miles south of my camp on Lake George.

On my return to the city I had better opportunities to learn of this species and the genus in general and have felt that a summary of what is known of this plant might prove of interest and value especially as rarely have I read of its occurrence in the same rings as *Marasmius oreades*. (Kaufman in his *Agarics* of

Michugan² mentions this) Naturally many fungi grow in rings, especially on flat untrammelled spaces, such as lawns, golf courses, etc., but the intermingling of these two species was very close and the identification perplexing, especially in partly dried specimens I had gathered some *Clitocybe* a few years previously on this same golf course, in the rough however, and had not seen it in the short clipped fields proper I had not determined it, but had noted its close resemblance in size, shape, color to *M. oreades*.

I append Peck's¹ description of *Clitocybe sudorifica* (Peck) in his New York Species of *Clitocybe* in which sixty-four species are described and in which Plate VII Figs 1-6 illustrations are offered.

Pileus fleshy but thin, broadly convex or nearly plane, often becoming slightly depressed in the center or umbilicate, irregular and splitting or lobed on the thin spreading margin, glabrous, watery white when moist, whitish or grayish white when dry, flesh watery when moist, white when dry, taste mild, odor none. Lamellae thin close, adnate or slightly decurrent, whitish, stem short, equal or sometimes narrowed at the base, glabrous or merely pruinose, stuffed with a white soft or spongy center or hollow when old, often curved, or somewhat flexuous, white or whitish, spores subglobose, 4-5 and 3-4 μ .

Pileus 2-4 cm broad 1-3 cm long 2-4 mm thick. Gregarious. Lawns and grassy places, Albany, Ontario, and Saratoga counties. September to November. Rarely the pileus has an obscure zone near the margin.

This species was at first confused with *Clitocybe dealbata* (Sow.), but after its sudorific properties were discovered it was designated *Clitocybe dealbata sudorifica*. Still further investigation led Ford and Sherrick to consider it worthy of specific distinction. Dr W W Ford found it sufficiently toxic to cause the death of frogs, rabbits, and guinea pigs, although it may be eaten by man in moderate quantities with no more serious results than a profuse perspiration, sometimes continuing five or six hours. It should be considered medicinal and unwholesome and avoided as food.

Ford and Sherrick's report on the toxic properties of the (Howland) type species sent them by Prof C H Peck of Albany (1911) is worth placing here.

Utilizing the Hamsen method of extrac-

tion they obtained from the final product which in small quantities dissolved in water gave characteristic muscarine action in frog's heart neutralized by atropine, thus confirming an earlier report made on testing a watery extract of a few specimens of the original Howland specimens. Here rabbits showed, in three to five minutes, profuse salivation, diarrhea, with later recovery. A guinea pig died in fifteen minutes, and another had paralysis of respiration.

W A Murrill² in 1915 contributed a review of the *Clitocybes* of North America where over a hundred species are described. With reference to *C. sudorifica* Murrill states he has examined the types (*C. dealbata* and *C. sudorifica*) and can see no morphological difference between the two plants. They both grow gregariously in exposed grassy places and the best observer could not tell them apart. Also with reference to Peck's species of *C. morbifera* allied in poisonous qualities with *C. sudorifica*, but more poisonous Murrill was unable to see any morphological differences from *C. dealbata*.

Dr L C C Krieger, whose recent splendid little Manual of the Fungi gave me the first clue as to the "sudorific" talents of this *Clitocybe*, wrote me the name of Mr Worthington Smith (Gardner's Chronicle of 1886) as offering the earliest report on the sweating powers of this fungus.

In this report (N Y Public Library) accompanied by an excellent sketch of *Agaricus (Clitocybe) dealbatus*, W G Smith states that he ate about a dozen specimens at breakfast. It was a cold morning and he had a fire in his dining room. A few moments after eating he felt very hot his hands began to perspire, then his face, and soon he was soaking wet from a copious perspiration. He changed his clothes. Was then cold, wrapped himself in a blanket and sat before the fire. After three-quarters of an hour the heat and perspiration came on with double force, the perspiration running in streams from his body. At midday the inconvenience had passed and he was left thirsty, drowsy, and weak. No further symptoms were noted. In a letter sent by the author to Dr Bull, the latter reports colliquative diarrhea from eating *Clitocybe nebularis*. Mr Smith notes that a second person who also ate of the *Clitocybe dealbata* was not so incon-

veniened. How many eaten by this second person is not reported. He christens the mushroom "The sweater."

The reports of the sudorific properties of *C. dealbata sudorifica* (Peck) by Peck are among the earliest in American literature. In his first report, (1911) Peck tells of having eaten *C. dealbata* for some time. This particular eating of eight specimens of *C. dealbata* sent him by a Mr. Howland from Saratoga Springs gave different results. They were fried in butter and eaten at supper. The taste was agreeable. In about half an hour he began to perspire, first appearing on the forehead, then spreading over the entire body. It continued for about five hours. No other disturbance was noted, maybe a slight quickening of the pulse, a mild rhinorrhea, some salivation, and an occasional hiccough. He went to sleep later and woke up in the morning as usual.

The following year Peck reports on poisoning from a closely related form which he christened *Clitocybe morbifera* from Washington, D. C., and from Michigan. It would seem to be more poisonous than *C. sudorifica*, having muscarine like properties.

In 1923 J. W. Roberts reports on being poisoned by *C. dealbata* gathered in Washington, D. C. He tried nibbling a few bits, also one entire specimen, with no unpleasant symptoms. He and his wife then ate eight or nine specimens creamed at dinner. He noted that he perspired a bit more than usual and he noted that there was some modification of the lights in an adjoining apartment. He gathered more and a day or so later ate twice as many. Shortly thereafter (15 minutes) he noted he could hardly distinguish objects and in forty-five minutes the hours on his watch were unreadable. He then noted half an hour after eating he became very warm and began to perspire freely. The perspiration continued. His wife also began to complain of inability to see and there was marked pupillary contraction. There was also diarrhea, and twitching of the legs. Perspiration of the entire body, wetting the underwear, salivation, rapid pulse ninety—seventy being the usual rate. Atropine was given and he went to bed with a hot-water bottle. He felt a bit exhilarated. The next morning he was well save there was some scantiness in

urination and some increase of the saliva and his taste was involved.

In a very interesting thesis by Martin Sans, I find several other cases. Thus (p. 126-127) a Dr. Duby of Lyon in 1923 reports two instances of discomfort from what was considered *C. detrusa* but was *C. dealbata*, (1) A child eating some had colic and a parrot died, and (2) his dog took about two teaspoonsful of sauce from the plate of mushrooms that he himself had eaten. They were *Boletus aurantiacus* and *Clitocybe dealbata*, about fifteen of the latter. Almost immediately the dog began to drool, later became depressed, thirsty, vomited, and later died. Dr. Duby was unaffected.

Another case of animal poisoning is reported by A. Pouchet of Lyon (Martin Sans, p. 127). M. B., a teacher and evidently a botanist, had been sent some mushrooms to determine. While studying them he noted one of his cats make several leaps and then fall down dead, next morning the other cat was found dead. He then investigated carefully and found that his specimens in the original basket had been freely eaten by the cats. They were *Clitocybe dealbata*.

M. C. (p. 128) an amateur mycologist and his wife ate an omelet with *Marasmius oreades* and *Clitocybe dealbata* for supper. An hour after going to bed Mme. C. began to sweat, salivate, and vomit. She vomited voluntarily and took a bowl of milk as an antidote. The perspiration continued for several hours with diminishing intensity. M. C. was much agitated, and sweat considerably while caring for his wife, but had no further trouble.

Mme. R. (p. 128) ate a mushroom omelet. Three hours later she had to go to bed with colicky pains, sweating, fainting, and general weakness, which persisted a few days. The mushroom was *Clitocybe dealbata*.

M. G. (p. 128) had eaten *C. dealbata* on a number of occasions without any inconvenience, as well as friends of the region, especially dried specimens. One day in July 1923 the family collected a quantity and they were eaten fried in butter without previous boiling. There were seven of different ages in the party. Five to six hours after, the first symptoms of poisoning appeared. They were those of vertigo and excitement, visual disturbances (diplopia) and weakness in the legs (legs of cotton), nausea and vomiting, cold sweat, coldness of the extremities, and diarrhea. Cold sweating was felt by all, sometimes after the feeling of weakness but mostly before. One woman who rarely perspired even in hot weather had an abundant perspiration. A man of

sixty and a nursing infant almost died Twenty-four hours later all were well

M. B. (p 130) railroad employee, and his wife walking along met a man collecting small mushrooms He assured them they were good to eat. They collected some, and later cooked them with fat and garnished them on an omelet, and a small portion given to their cat. They had just eaten some of the omelet when the cat suddenly vomited violently, with salivation, had a running nose, and hiccough-like respiration At first they thought some neighbor had poisoned the cat, but M B in his turn began to be indisposed, some ten minutes after eating some of the omelet. His eyesight became involved, felt suffocated sweat abundantly, first on the forehead and then over the entire body Vomiting was induced by salt water

Then Mme B (p 131) who had only eaten slightly of the omelet was taken sick in the same manner but in much milder form

When seen by Dr Oulie an hour after he was taken sick M B's face was cadaverous, pupils markedly contracted, vision abolished, intense dyspnea, prodigious sweating, dry tongue, pulse imperceptible, cold and parietic extremities Anuria, no gastric disturbance, some diarrhea without colic Acetate of ammonium was given with quick response and slow recovery After eight hours patient perceived light, two hours later perspiration ceased, and next day save for some palpitations he was as usual

The cat also recovered although purged, salivated, sweated, and had hiccoughs

Dr Martin-Sans recites some of his own experiences with the mushroom eaten by M B the railroad man (p 130) with a cat who avidly started on the fried mushrooms but soon stopped. Chopped with meat more was eaten Indisposition soon followed, with cough, urination, vomiting, and defecation. Ptialism pronounced, contracted pupils, jerky movements, and finally slow respiration and death in about an hour Autopsy showed marked congestion of most of the organs of the body A second and third cat died with similar symptoms and similar findings

In his discussion of the poisoning Martin-Sans (p 140 et seq) notes that *Clitocybe dealbata* has been highly recommended by many mycologists He also writes of its growing in close association with *Marasmius oreades* In the case of M B he speaks of a mixing with *Rhodopaxillus sordidus* Martin-Sans is inclined to follow Murrill in saying that morphologically *C sudorifica* does not differ from *C dealbata* In most of the cases the sudorific action

is emphasized Martin-Sans found evidence in some of his animal experiments of a hemolysine, contrary to the findings of Ford and Sherrick (p 141) Here is something to study further In man the poisoning does not seem dangerous but the animal experiences should make one very cautious about this mushroom

Clitocybe rivulosa (Pers) Quel, a widespread European species, Peck found in the Adirondacks (Murrill p 270) and Martin-Sans devotes a number of pages to its properties (143 et seq) In the first place it closely resembles *C dealbata* and Martin-Sans raises the question of its specific rank *C Nuptunea* (Batsch) Fr *C phyllophila* (Fr), *C pithyophila*, (Secr), *C connata* (Schum), *C opaca*, with *C cerussata* (Fr) are considered by Constantin & Dufour⁴ as but variants of *C dealbata*, but most mycologists are of a different opinion Thus nearly all of the small white *Clitocybes* of the open fields come under suspicion *C rivularis* also has been collected intermingled with *Marasmius oreades*

Most European sources cite *C rivularis* as poisonous There are some who have found it not so Martin-Sans, Roch, and others, have reported cases of poisoning of *C rivularis* Wiki and Roch add *C candicans* to the list of the suspicious *Clitocybes*, *noycebe infida* (Peck) (See Murrill) Dr Deming of Westchester Sweating, no nausea nor vomiting Full head as in nitroglycerine beating heart This is a yellow spored variety of the *C illudens* group

In the therapy of poisoning prompt evacuation of the stomach and intestines is called for Hypodermic injection of atropine or oral use of the tincture should follow Alcohol is contraindicated Specific sera are being evolved but are rarely available Neutral salt solutions in the veins has given prompt results with one or more poisonous species of mushrooms, also a 4 per cent solution of dextrose used intravenously to overcome hypoglycemic shock which occurs in some cases of poisoning

NONTRAUMATIC CYSTOSCOPY

I BAYARD CLARK, M D, *New York City*

Not long ago I was invited to look after the urological work of a hospital in one of the small but exclusive communities that fringe the City of New York and was soon made aware of the apprehension and fear that attended all cystoscopic procedures in that locality. The phobia included the doctors and nurses, and extended out into the community. One caught whispered comments of the excruciating symptoms that followed these "fearful" ordeals.

Unfortunately the first few patients I found it necessary to cystoscope there audibly and protestingly reflected the general feeling about cystoscopic examinations. They had "gone through" the experience before.

It appeared to be the customary thing in this hospital to have these patients prepared for general anesthesia "if necessary" although local anesthesia was more commonly employed. And the patient was sent to bed for varying periods, to "recover."

The most interesting example of this widespread dread was exhibited by an ex-operating room nurse who was to be cystoscoped. I entered the room to find her blanched and trembling on the table, about which stood some eight or ten sympathetic nurses looking very grave. Taking in the situation I began talking airily of some current topic of general interest. My ruse was about as welcome as a jig at a funeral. But I kept up the lightsome talk until the cystoscope had been safely lodged in the bladder. As its introduction, sans any anesthetic, had occasioned no discomfort to the patient it immediately occurred to me that the patient herself and her condoling companions might not believe the evil deed had been done. So I invited the intern present to sit down at the eyepiece and describe what he saw in the bladder. Thus the tension in the room subsided and the job was quietly completed.

Shortly after this encouraging experience a little experiment in nontraumatic cystoscopy was instituted to reestablish, if might be, the morale of the place in regard to these essential examinations.

A series of fifty-six consecutive cases was carried through without the use of any anesthetic, local or otherwise, except in the case of one little girl aged six who it was feared might not cooperate. None of these patients was sent to bed to "recover" except the little girl. There were thirty-one males in the series and twenty-five females. The age range was from six to seventy-six years. Five cases had colicky pain for an hour or two which was ascribed to the pyelographic media. In two cases—devitalized subjects—there was discomfort lasting the day. Beyond this there were no reactions or complaints of any kind in this series. One cannot always be so fortunate, for as every urologist knows there are the difficult cases that do come along every now and then to try our souls and make cystoscopy seem like a rather formidable affair.

I have recounted this particular personal experience in the small community as I found it, not because it shines out as a rare example of cystoscopic work in like places, but because according to all my previous observations it is very much the kind of cystoscopy one commonly finds under similar circumstances.

There are perfectly good reasons why this should be so. This work is usually taken on as a side line by some conscientious practitioner with a leaning toward surgery who very rightly thinks someone should look after these obviously urological cases.

When the numbers of such cases are counted up in any given small community there are not enough of them for anyone to gain proficiency, or sustain proficiency gained in any postgraduate course in cystoscopy that might have been taken. It is not only impossible to keep one's hand in, it is impossible to keep one's head in and cultivate any useful degree of urological judgment in the cases easily recognized as such.

But experience alone does not seem to be the only factor in producing a competent cystoscopist. There are a good many from whom nature seems to with-

hold that elusive quality of touch which robs urethral instrumentation of its sorry consequences. "Some men simply haven't the 'flair,'" as I once heard a noted teacher express it, "so I try to persuade them to take up some other branch of medicine."

Eleven years ago I published an article ("Gentleness in Genito-Urinary Surgery" *JAMA*, April 17, 1926) and from which I received many appreciative letters from various sections of the country.

This article of a decade ago grew out of ten years' experience at Bellevue Hospital, two years in war service, several subsequent years in other New York Hospitals, and a busy urological practice, during which time I had learned what a large proportion of his work comes to the specialist in urology from instrumentation—catheters, sounds, and cystoscopes—in unaccustomed hands. The art of the catheter still seems to be a closed book to the medical profession at large, and Frank Kidd, the noted London urologist, declared years ago that every sound in the possession of a general practitioner should be thrown into the smelting furnace. The record of the amateur cystoscopist is a story of its own that has been permanently impressed on the delicate structure of countless urogenital membranes.

The present article is advantaged by ten more years of experience which tallies in all essential respects with its predecessor and it does seem unfortunate that all this avoidable damage, suffering, and infection, and the many escapable operations, with their consequent disability of vital function, should not be brought into the focus of more intelligent consideration by our profession.

How is our problem to be solved? For over half a century the delicate work about the human eye has been universally respected by the medical profession, and left to those who by natural bent and conscientious training have fitted themselves for their special task. The physician thinks nothing of sending his patient who requires the skill of an ophthalmologist any distance in order to get proper care, yet the genitourinary organs have been the sport of pretty nearly all doctors, especially the young ones just

beginning practice. Why? Because modesty or shame, call it what you like, compels the sufferers to endure the most outrageous treatment for their genitourinary ills *in silence*. And of this safeguard—and I loathe the saying of it—many medical men take advantage. This has always been a serious consideration standing in the way of competent urology. But in the larger cities it seems to be getting less acute, probably because the people themselves are waking up to this black spot in medicine. In the smaller communities it still finds fertile soil upon which to flourish. The sexual infections especially—gonorrhea and syphilis—have always been an inviting target for the inexperienced beginner in the practice of medicine to pop at. This is undoubtedly one reason why these infections have so completely run away with us, and have now perforce called forth a national campaign to bring them under control.

This has nothing to do with cystoscopy which is the subject of this paper, but it is linked up with it in the absence of qualified urologists in the smaller communities who might function effectively in bringing order out of chaos in this field.

In this particular article I have tried to direct our chief attention to the cystoscope because that still remains the master key to the puzzles of urology, and is the starting point from which we most often must initiate appropriate therapeutic measures. Urography has come to be an exceedingly important adjunct to diagnosis but it will always be overshadowed by the cystoscope. It can never be a complete substitute for that instrument in revealing urological pathology.

I have tried to show that the patient in the smaller communities does not get the full benefit of qualified urology which is now a well-developed and mature branch of medicine. Indeed, the patient very frequently gets something far worse than the complaint for which he seeks relief.

Is there any remedy for this unhappy state of affairs? I believe there is a comparatively simple one.

The taking on of this part-time urological work in the small but typical community while pursuing my practice

in the city has enabled me to make a useful and impersonal comparative study of urology as it is conducted as a complete specialty in the city and as an incomplete specialty out of the cities. It has given me very definite data regarding the uneconomic and physically detrimental results of the work done in the smaller communities by men only partially equipped for this very necessary part of medical practice.

Now the real difficulty seems to lie here. The incidence of urological disease per capita is actually a very small one. The morbidity in this field of medicine is, I believe, only about two or three per cent of the total morbidity. In a single small community there isn't enough to give a full time urological specialist a living, therefore the work is done in a haphazard way by some doctor who is really giving his best thought and attention to some other kind of work. This does not go in urology, it is an exacting master of one's time and intelligence.

The "certification" of the urologist is a very decided step forward, and it is going to be a great help in solving the problem of bringing competent urological assistance to the smaller communities. The certified urologist will give the assurance of qualified service. But if there isn't enough work to keep him busy in a small community, how is he to be maintained there? He is to be induced there by rousing one small community and its hospital to act as a urological center for a certain number of surrounding communities, enough to bring in sufficient work to keep a first class urologist interested, and sufficient work to make urological technics a routine procedure.

I have been trying to work this plan out in the community I have alluded to, hoping that we might arrive at some useful basis for general application in all like small communities. There is nothing very startling about the idea. It must have occurred to many other urologists in their efforts to find some way of giving people, not in the larger centers, an even break in this branch of medicine.

This article isn't written to tell front rank urologists anything they do not already very well know. It is an appeal

to the rank and file of medical men to turn a little serious attention to the existing unfortunate situation. It is not necessary to dwell on the physicians obligation to society. I know of no profession more keenly alive to professional responsibilities. It may be characteristic of commercial business to get all it can out of society without counting the costs to human welfare, but this certainly is not so in our profession. We rest on ancient traditions of a very widely different nature, and if physicians at large will only come forward in their true colors they will be able without a great deal of difficulty to work out this plan whereby the people of their own communities can be provided with safe, serviceable, and "certified" urology.

This too will be of immense service to the present efforts of the United States Public Health Service which through the rare talent and ability of its Surgeon General is trying to organize a comprehensive system of orderly and effective clinical and outpatient treatment for the sexual infections in every community in the land. This public health work will be greatly advantaged if there is a spread of responsible urologists to assist in it.

Conclusions

1 Traumatism is unnecessary in cystoscopic examinations just as it should never occur in other urethral instrumentation.

2 Local anesthesia leads to traumatism because it blunts the sensibility of the patient, which is the surest guide to its avoidance.

3 Anesthesia is rarely necessary.

4 Reactions should rarely occur, and infection or injury to the urethra or bladder never.

5 Cystoscopy if properly performed should be accompanied with little or no discomfort in the great majority of cases.

6 The career of the cystoscope has been toward a progressively reckless use of that instrument.

7 It would be preferable to have competent urological work instituted by the medical profession rather than have it demanded by the public.

PROTAMINE ZINC INSULIN

Clinical Experiences

JAMES FINLAY HART, M D, *Bronx*

Opportunity to study the effects of protamine zinc insulin in diabetes was made possible by the generosity of the manufacturers. Twenty-three patients on the metabolic ward of the New York City hospital were picked as suitable cases and for periods varying up to four months received the protamine zinc in place of their usual insulin. There were also three ambulatory patients attending the Midtown hospital clinic who took the protamine zinc for over eight months. Our experiences with these twenty-seven cases are the basis of this paper.

The twenty-three hospital patients were under very close supervision with weighed trays and four fractional urines a day. The ambulatory patients were severe cases that were picked as being highly cooperative. Conditions then, on the whole, were somewhat above the average clinical control which made it seem a fair test for any noticeable improvement due to a change in therapy.

In selecting and preparing patients for this test certain groupings became apparent. It was easy to recognize mild, intermediate, and severe cases. We considered those taking up to twenty units of insulin a day in the mild group, those taking from twenty to forty in the intermediate, and those taking over forty in the severe group. As a rule the mild group got along well on one injection a day, the intermediate and the severe on two.

A subdivision in the intermediate and severe groups could be made. The majority of cases in either group were easy to balance and easy to keep there. There were several cases however that were interesting because they exhibited such a perfect balancing ability. One case was especially so. The following is the history

CASE 1 Mrs E C sixty-five years old, had no knowledge of diabetes on entering the hospital March 29, 1928. She was put on a "low carbohydrate" diet and twenty units of insulin before breakfast. From her

entrance to the present date she has been a notorious cheater. She has for three years eaten what she wanted when she wanted it, seemed to thrive thereby, and good naturedly refused to change her ways. Her insulin dose crept up to 50-0-15 by 1934 and to 69-0-42 during the early half of 1936. On Sept 12, 1936, the date of the first blood sugar curve she had been controlled for a number of weeks and was then taking insulin 72-0-45 with an "official" diet of C 130, P 74, F 76. Under the above regimen she was sugar free and without shocks. Incidentally she never had one shock during her eight years stay in the hospital. In addition, during the two months she was under protamine zinc treatment marked changes were made in the dosage without either a spill or a shock.

In the same group were several elderly diabetics that were, for a long time, inmates of the less active chronic medical wards. Because their diet was satisfactory and because they neither shocked nor spilled they had been kept on the same insulin dose for years. It was found that their dosage of insulin could be cut down to one-half or one-third without any clinical change. The inference is that their tolerance had improved since their last adjustment. It could be that the higher doses of insulin are optimum for these patients, but it definitely showed that they had a very marked range between the minimum and the maximum dose.

In contradistinction to the former group were the hard to balance cases. In the city hospital there are always two or three such patients and roughly speaking they constitute about five per cent of the diabetic population of the institution. While some of these may cheat it would be impossible for them to be the cheat that Case 1 is known to be. The following case is an excellent example.

CASE 2 W M, seventy years old was admitted July 9, 1935 with a history of diabetes for twelve years. He is a pleasant cooperative patient somewhat senile mentally and unable to get out of a bed or a chair.

in the city has enabled me to make a useful and impersonal comparative study of urology as it is conducted as a complete specialty in the city and as an incomplete specialty out of the cities. It has given me very definite data regarding the uneconomic and physically detrimental results of the work done in the smaller communities by men only partially equipped for this very necessary part of medical practice.

Now the real difficulty seems to lie here. The incidence of urological disease per capita is actually a very small one. The morbidity in this field of medicine is, I believe, only about two or three per cent of the total morbidity. In a single small community there isn't enough to give a full time urological specialist a living, therefore the work is done in a haphazard way by some doctor who is really giving his best thought and attention to some other kind of work. This does not go in urology, it is an exacting master of one's time and intelligence.

The "certification" of the urologist is a very decided step forward, and it is going to be a great help in solving the problem of bringing competent urological assistance to the smaller communities. The certified urologist will give the assurance of qualified service. But if there isn't enough work to keep him busy in a small community, how is he to be maintained there? He is to be induced there by rousing one small community and its hospital to act as a urological center for a certain number of surrounding communities, enough to bring in sufficient work to keep a first class urologist interested, and sufficient work to make urological technics a routine procedure.

I have been trying to work this plan out in the community. I have alluded to, hoping that we might arrive at some useful basis for general application in all like small communities. There is nothing very startling about the idea. It must have occurred to many other urologists in their efforts to find some way of giving people, not in the larger centers, an even break in this branch of medicine.

This article isn't written to tell front rank urologists anything they do not already very well know. It is an appeal

to the rank and file of medical men to turn a little serious attention to the existing unfortunate situation. It is not necessary to dwell on the physicians obligation to society. I know of no profession more keenly alive to professional responsibilities. It may be characteristic of commercial business to get all it can out of society without counting the costs to human welfare, but this certainly is not so in our profession. We rest on ancient traditions of a very widely different nature, and if physicians at large will only come forward in their true colors they will be able without a great deal of difficulty to work out this plan whereby the people of their own communities can be provided with safe, serviceable, and "certified" urology.

This too will be of immense service to the present efforts of the United States Public Health Service which through the rare talent and ability of its Surgeon General is trying to organize a comprehensive system of orderly and effective clinical and outpatient treatment for the sexual infections in every community in the land. This public health work will be greatly advantaged if there is a spread of responsible urologists to assist in it.

Conclusions

- 1 Traumatism is unnecessary in cystoscopic examinations just as it should never occur in other urethral instrumentation.
- 2 Local anesthesia leads to traumatism because it blunts the sensibility of the patient, which is the surest guide to its avoidance.
- 3 Anesthesia is rarely necessary.
- 4 Reactions should rarely occur, and infection or injury to the urethra or bladder never.
- 5 Cystoscopy if properly performed should be accompanied with little or no discomfort in the great majority of cases.
- 6 The career of the cystoscope has been toward a progressively reckless use of that instrument.
- 7 It would be preferable to have competent urological work instituted by the medical profession rather than have it demanded by the public.

the second curve was done. We found a lowered fasting blood sugar—possibly too low. The breakfast is not so quickly dispensed with but the supper peak is well within normal. It can be seen in these cases that the same number of units are more effective, have a more prolonged action, and preserve a better blood sugar balance than that of the regular insulin.

Intermediate Group

Let us consider now the effect on the intermediate group. Where there was a substitution for all or part of the regular insulin in one or both injections a noticeable drop in the before breakfast blood sugar was seen. Other than that there was little improvement in the curves. In none of our cases was there any reduction in the number of units or injections. The following cases are illustrative.

CASE 4 C D, age fifty-seven, was admitted May 20, 1935 with no knowledge of diabetes. He was put on a diet of C 180, P 80, F 118, making a total of 2115 calories. This was controlled by insulin 25-0-20. For several months he required seventy-five units of insulin a day for a balance but for two months before the first curve with a change in the diet to C 150, P 78, F 83, he kept sugar free on insulin 20-0-5.

The first curve was taken on September 9, 1936. He was then put on a combination of regular and protamine zinc insulin, ten and fifteen units respectively before breakfast. After fourteen days, a curve was made and it showed a favorable change, the fasting blood sugar was down thirty points. This showed that the same number of units of protamine zinc were more potent and caused a more sustained action than that of the old alone. The daily blood sugar curve gave less spiking with the combined dose. On September 24 he was put on twenty-five units of protamine zinc alone before breakfast. After five days, a second curve was taken with results not so striking. The supper was not as well-controlled. Then on September 30 he was changed to protamine zinc twenty-five before supper. After fourteen days the fourth curve was taken and the breakfast caused a high peak. In this case, a combination dose before breakfast was the most efficient form of administration.

CASE 5 A T male, age fifty-eight was admitted to the hospital October 24 1936.

He knew for ten years that he had diabetes but said that he never needed insulin. He was put on a diet of C 180, P 80, F 60, and was shortly balanced with insulin 20-0-15. The first curve was taken on January 9, 1937. He was then given fifteen units of regular insulin before breakfast and fifteen of protamine zinc before supper. The breakfast and the supper was not as well taken care of but the before breakfast blood sugar was down thirty points.

CASE 6 J W, male, age fifty-eight, was admitted to the hospital February 7, 1936 with a history of diabetes for ten years. On entrance he was put on a diet of C 150, P 80, F 95. On September 9 the first curve was taken. He had been on 30-0-5 units of regular insulin for over a month without a spill. The next day he got one dose of thirty-five units of protamine zinc before breakfast. For thirteen days he continued this, showing a slight spill in the second or third urine. Then the second curve was made and very little change was seen. Following that he was twenty-one days taking thirty-five units of protamine zinc before supper. There was very little change here except that there was a lower before breakfast blood sugar.

CASE 7 M F, age forty-two, was admitted November 9, 1934. She had been aware of her condition a year and a half before entrance. She was put on a diet of C 200, P 80, F 110 with regular insulin 35-0-20. On September 16 1936 she had been well-balanced on C 152, P 78, F 75 with insulin 29-0-7 for almost two months. The first curve was done on this day and she was then given protamine zinc 29-0-7. There followed slight traces of sugar in the first and second specimens until October 13 when the second curve was made. There was no improvement from the protamine zinc, rather there was a poorer response after breakfast and supper. Following that she was given thirty-six units of protamine zinc before breakfast. There followed a continuous spill throughout the day which necessitated raising the protamine zinc to 45-0-0, which brought some improvement. On November 10 the third curve was taken. On that day there was a spill of 0-1-0-0.

Severe Group

The severe cases in the easy to balance group showed a tendency toward a better before breakfast blood sugar when the same number of units of protamine zinc were substituted for the evening dose of regular insulin or where part of the breakfast insulin was given in the form of protamine zinc. The following case is illustrative.

without help. Partially because he was such a difficult problem with persistent heavy spills and frequent severe shocks and partially because he was such an appreciative person he became the patient of interest of each succeeding intern.

In practically his whole stay in the hospital he received four injections a day. For fourteen months with regular insulin there did not seem to be any arrangement of dosage that would bring about a balance. Because he could not leave his chair it was impossible for him to cheat. Also because his daily food intake was constant and his muscular exercises without change, one could not blame either of these factors. One or two units of insulin would change a four plus spill to a shock. Although he might have five or six shocks a week he would have them at different times of the day. Several times after he had been shocking heavily we cut the total daily insulin down and let him spill freely. In a few days the spill would usually clear up without further aid. It would remain clear for a few days and then go back to a heavy spill for a period. It seemed as if some cycle was in action and as such it appeared as a competent explanation for the difficulties encountered in arriving at a balancing dose of insulin.

In groups of diabetics, one finds then, mild, intermediate, and severe types. Under prolonged hospitalization a noticeable number show a gradual continuous improvement in tolerance sufficient enough at times to move a severe case into the mild class. Most cases are easy to balance. There are a few, however, who exhibit extraordinary balancing ability and likewise a few who are impossible to stabilize. Again in the easy to balance group there are some that have a wide range between the maximum and minimum insulin doses.

Objectives in the Study

We took as objectives in this study the conclusions commonly held by authors in articles on protamine zinc published during 1936. The following points were stressed.

1 The action of the insulin was prolonged

2 A better blood sugar balance was created

3 Fewer units of insulin were needed

4 Fewer injections were needed.

5 A 100 gram error in the carbohydrates of the diet would be taken care of

Because we found the effect of protamine zinc varying with the intensity of the diabetes we will consider the mild, intermediate, and severe groups separately.

Mild Group

Taking the mild group first we find that protamine zinc was an improvement over the regular insulin. It could be easily shown that the protamine action lasted longer than that of the old form. A better fasting blood sugar was frequent and a better blood sugar curve was the rule. There seemed to be an accumulative action about the fifth day, and a slight drop in the number of units was frequently necessary. After several months of protamine zinc, however, the units were about the same as with the regular. There was no improvement in the number of injections as these cases only required one injection a day. We quote the following case.

CASE 3 G. K. was admitted October 28, 1935 without previous knowledge of diabetes. His toe was amputated on December 16 and the leg removed on January 8, 1936. After entrance he was balanced on insulin 20-10-15. He was kept on this insulin dose until September 9 when it was changed to 15-0-0. No spill occurred from this change so a curve was done three days later. On the next day protamine zinc was substituted and on the 23rd a second curve was taken. There was no spill or shock from the protamine zinc and throughout the test his diet was 2049 calories a day with C 204, P 90, and F 97.

This is a mild case that had a range for insulin between 20-10-15 and 15-0-0. Adjustment was made before the first curve was done. On analysis the curve shows a normal fasting blood sugar. The fifteen units of old insulin takes good care of the breakfast. The lunch is likewise controlled, but supper is too much and the blood sugar rises to 210. After ten days of protamine zinc substitution

Our other group in the severe class, the hard to balance cases, showed no improvement from any form of substitution with protamine zinc. All possible combinations were tried on Case 2 without avail. This man is as much a problem today as he ever was.

The ambulatory group which were also severe cases acted as follows

CASE 9 A P, age seventeen, had diabetes for eight years, complicated with rheumatic fever and cardiac sequelae. For two years after his last rheumatic attack he averaged 140 to 150 units of insulin a day. He was on a high carbohydrate, high calory diet, and spilled and shocked frequently. For about a year before trying protamine zinc he lived an active boy's life during which time he needed only from seventy to eighty units a day. He took fifty units before breakfast and twenty-five to thirty before supper.

In July he substituted protamine zinc for the evening meal. There was no apparent change. For seven months this routine was continued. There would be periods of spill before and after breakfast similar to that with the old insulin. Because of a lack of supply he had to go back on the regular insulin for about ten days. It seemed to him that the morning spill was more frequent with the old insulin.

CASE 10 The second ambulatory case was W K., age thirty-eight who was difficult to balance in part because he was a porter doing hard work with shifting working hours. He would have spills and shocks frequently but did best on thirty-two units before breakfast and twenty-eight before supper. He was on a high carbohydrate high calory diet and in all seemed an ideal case for protamine zinc.

We noticed at first that he could not control breakfast with protamine as it did not work fast enough. We compromised then with the old insulin for breakfast and protamine zinc for the evening meal. We lowered the units of protamine zinc for fear of the cumulative effect but after a month or so he had to return to twenty-eight units of protamine zinc before supper. For the last seven months he has been taking thirty-two units of regular insulin before breakfast and twenty-eight of protamine zinc at night. During this time he had the longest shock ever seen by us. It lasted over six hours during which time he bruised himself severely. He was very pleased at the end of eight months to return to the old insulin.

CASE 11 The third ambulatory case was brought to the hospital in a coma. This was

precipitated by an upper respiratory infection. It took over two months of close observation to get the patient in good enough balance to try the protamine zinc. The evening dose of the regular insulin was changed to the same number of units of protamine zinc. He left the hospital directly after the change but appeared regularly at the clinic. Outside he worked almost twelve hours a day as a salesman and during the three months gained about twelve pounds. Throughout this period he gave evidence of a subacute nasal infection. On leaving the hospital he was getting thirty-five units of old insulin in the morning and twenty units of protamine zinc at night. His business took him to Florida and at that time he was taking thirty-five units of regular insulin before breakfast and fifty-five of protamine zinc before supper. He did not shock but spilled considerably. This lowering of the tolerance was undoubtedly due to the nasal infection.

Summary

It is essential that a careful selection and preparation of patients be made before any comparative study of regular and protamine zinc insulin is begun. First the degree of severity must be considered. Mild, intermediate, and severe cases are easily recognized and treatment such as the number of units of insulin together with the number and time of injections vary with the intensity of the case. Again, as happens in a large percentage of our cases, long continuous hospitalization under diabetic regimen brings about an improvement in the tolerance so that severe diabetics may move into the intermediate or even into the mild class. On the other hand some cases advance from the less to the more severe group. Acute infection increases the severity while subacute infection prolongs this state over long periods. It is a common occurrence therefore for slow continuous improvement in the tolerance under hospital care with the regular insulin.

Furthermore certain cases are noticeably easy to balance while others, mostly in the severe groups, are apparently beyond our present day skill. Certain individuals exhibit a marked range between the maximum and minimum insulin dose while others are susceptible to one unit of insulin. All those cases with a wide range should be recognized and an adjustment should be made bringing them

CASE 8 P K, age eighty-seven, was admitted November 12, 1936, with a history of diabetes for twenty-five years. Shortly after admission he became regulated on a diet of C 125, P 72 F 110 and forty-four units of regular insulin before breakfast. There was an occasional trace of sugar in the urine. On January 9, 1937 the first curve

was done. The next day a substitution of forty-two units of protamine zinc was made and there was a slight improvement in the spill. Ten days later a second curve was made and this showed a lowering of the before breakfast blood sugar and a poorer response to the breakfast. Otherwise the curve was about the same as the last.

TABLE I

PRACTICAL ASPECTS OF GALL-BLADDER DISEASE

JOHN RUSSELL TWISS, M D, *New York City*

My remarks herein will be limited to a few facts of practical clinical importance in the diagnosis and treatment of some of the more common disorders of the gall-bladder. The conclusions are the result of an investigation begun with the collaboration of Dr Chas Gordon Heyd and continued during the past seven years in the combined Medical and Surgical Gall Bladder Clinic of the New York Post Graduate Hospital, under the direction of Dr R. Franklin Carter. During this period about 2000 patients suspected of gall-bladder disease have been studied, over 200 of which have come to operation.

Prevalence and Importance Disease of the gall-bladder is considered the most common cause of digestive symptoms. While all patients with this condition should have a careful diagnostic work-up and medical supervision, a certain number require surgical intervention. The proper selection of these patients for operation constitutes one of the major problems of medicine. While we do not approve of prolonged ineffective medical treatment in cases of advanced infection and pathology it is at the same time unfortunate for both patient and doctor to find the patient unrelieved of his symptoms following a major operation.

Diagnostic work-up The best insurance against regrets is a complete initial diagnostic work-up. Routine histories of these patients are usually indefinite rather than characteristic, the commonest symptoms being pain other than colic, discomfort after meals, distention, belching, nausea, vomiting, and an intolerance to fats, in our experience jaundice, colic, chills and fever are relatively less frequent. The physical examination in the absence of active infection or obstruction is commonly of little assistance.

Differential Diagnosis In view of the diverse symptomatology of disease of the gall-bladder, other possibilities in differential diagnosis must always be borne in mind. Among those conditions which we

have found most frequently leading to difficulties in diagnosis are appendicitis, duodenitis, peptic ulcer, pylorospasm, mucous colitis, pyelitis, and stone or stricture of the urinary tract. Allergic conditions, as suggested by the presence of hay fever or asthma, may give similar symptoms.

Cholecystogram The cholecystogram, one of our most useful diagnostic procedures, should be done in every case of suspected gall-bladder disease. While normal visualization and emptying of the gall-bladder occurs in most cases in which there is no pathology, in seven per cent of our patients in whom this finding was reported, stones were found at operation. Lack of visualization of the gall-bladder, as interpreted by Dr William H Meyer, Director of the Department of Roentgenology, is considered of significance only if the double dye method is used and the dye is seen normally distributed in the colon.

Among the conditions besides infection frequently preventing visualization of the gall-bladder are cystic duct obstruction (particularly by stones), liver pathology, and common duct obstruction. The latter conditions are usually associated with jaundice, with which there is in our experience rarely visualization of the gall-bladder. It is furthermore worthy of note that in certain patients, particularly those having a nervous temperament, there may be no visualization of the gall-bladder on repeated examinations, with no apparent pathology of the gall-bladder found at operation.

Biliary Tract Drainage Biliary tract drainage is at present generally conceded to be a valuable supplementary method of diagnosis, provided that the drainage and the examination of specimens are in the hands of experienced workers. Drainage is done on every patient coming to our clinic, its diagnostic accuracy as checked at operation compares most favorably with that of the cholecystogram. The use of gall-bladder drainage is strongly

Read before the New York County Medical Society, February 23, 1937

down to the minimum dose before the protamine zinc is used

It is likewise important to recognize that factors other than diet and insulin influence the blood sugar. Mains and McMullen¹ showed the importance of sympathetic nervous disturbances, the function and dysfunction of the endocrine glands, alimentary absorption, and infection as factors in its regulation. They noted a daily curve on any one individual might remain constant for several days and be followed by a radically different curve, and they felt this was due to the addition of one or more of the intercurrent factors. Mollerstrom² also brought out this fact stating that there is a physiologic rhythm of the carbohydrate metabolism of the liver which is independent of the diet and of insulin. This rhythm, he showed, varied in different individuals and in the same individuals on different days.

Conclusions

It seemed to us from the evidence at hand that in all grades of diabetes, protamine zinc produced a decided lowering of the before breakfast blood sugar. We inferred that this was due to a more prolonged action of the protamine zinc.

The most apparent effect of protamine zinc on the blood sugar is during a fast. This is noticeable in the normal daily fast that exists from about three hours after supper to breakfast. When a rise occurs in the blood sugar of diabetics at this time it is produced by factors other than the diet, it is slow and gentle and varies with the intensity of the case. The protamine zinc gradually liberating the insulin equalizes the slowly rising blood sugar and brings about a better before breakfast blood sugar.

We conclude that protamine zinc acts as a factor in blood-sugar stabilization. We feel however that it is a limited factor capable of recognition only when the dysfunction of the sugar metabolism is mild. In those cases of diabetes that have only a slightly elevated blood sugar after a meal and only require small doses of insulin for a balance the effect of the protamine zinc will be evident. In the severer ones however, where the meals

produce a sharp and extreme reaction on the blood sugar, the protamine factor is too feeble.

Reduction in the number of injections was not possible in any of our cases. The mild cases with their one injection a day obviously could not be changed. When cases were severe enough to require two or more injections a day of the regular insulin they usually exhibited a sharp pronounced rise of blood sugar after breakfast. Protamine zinc alone was not rapid enough to control this. Effort was made to equalize both supper and breakfast blood sugar rises by one dose of protamine zinc before supper. This was not successful in any of our cases because of the rapid rise of the after breakfast blood sugar. Being convinced that the breakfast and supper rises of blood sugar could not be controlled in the severer cases of diabetes with one injection, we considered the advisability of using the two insulins in conjunction. We tried the original idea of Hagedorn by giving the regular insulin in the morning and the protamine zinc at night and the later method of giving the two at once before breakfast. Both of these methods met with some success. We felt that protamine zinc given before breakfast in doses amounting to about one-half of the total breakfast units or before supper in doses equivalent to the regular insulin affected the before breakfast rises in most cases.

We did not find it possible to permit a leniency of 100 grams of carbohydrate in the diet while using protamine zinc. In fact we felt that the same strictness must be used as is customary with the regular insulin.

From the aforementioned one might say that protamine zinc could be used to advantage in all mild diabetics, and in the more severe showing a high before breakfast blood sugar.

to have an acutely inflamed tender distended gangrenous gall-bladder, practically ready for perforation, with a normal temperature and blood count. An initial subacute attack, however, may subside and the gall-bladder return to an apparently normal condition. A careful check-up for stones is essential in these cases, after the subsidence of the acute symptoms.

Surgical Jaundice. Another serious problem frequently coming to our attention is that of prolonged jaundice. The usual maximum duration of the so-called catarrhal jaundice is six weeks, any jaundice extending over this time is entitled to an immediate surgical consultation. The importance of liver damage and impaired function from prolonged obstruction cannot be overemphasized.

Among the most common causes of prolonged jaundice are common duct stones, malignancy, and pancreatitis. Probably the most accurate test for complete common duct obstruction is the absence of bile upon duodenal drainage, when the position of the tube has been checked by the fluoroscope. The relationship of the common duct stone with "sand" of calcium bilirubinate and colon organisms in the duodenal bile has been mentioned. Blood may be found with malignancies. The diagnosis in many cases must rest upon continued observations, repeated drainages, and repeated icterus index determinations.

Medical Management

General. Every patient with disease of the gall-bladder should in our opinion have medical supervision, regardless of the necessity of surgical intervention. The principal reason for this statement is the number of patients referred to our clinic with severe indigestion following the removal of the gall-bladder, who have been told to "eat anything they want." Few of these patients have evidence of stone or stricture. Many are entirely relieved by a proper dietary and hygienic regime, together with such medication as may be indicated by the diagnostic work-up.

Dietary. For many reasons diet seems one of the most important of all therapeutic measures in cholecystitis. Many varieties of gall-bladder disturbances do

not lend themselves equally well to the old style single type of "low fat diet." In the presence of cholelithiasis, hypercholesteremia, or active infection, the low cholesterol low fat diet is undoubtedly best. However in those patients having an enlarged atonic distended gall-bladder, in the absence of the findings previously mentioned, best results are frequently obtained with a stimulating type of diet, relatively high in fats and cholesterol. For those patients with a gastric hyperacidity, duodenitis, gastric irritability, or pylorospasm, a modified Sippy type of diet, high in carbohydrates and with intermediate feedings, gives excellent and at times dramatic results.

The importance of diet in patients treated surgically must be emphasized. The patient "afraid to eat" frequently presents himself for operation in a state of both dehydration and emaciation, a most discouraging operative risk. The essential preoperative preparation includes the forcing of fluids and the strict observance of a diet high in carbohydrate value, preferably with the addition of sugar, to build up the glycogen reserve of the liver. On the other hand the cases of extreme obesity commonly found to be in need of surgery, may be greatly benefited by a preliminary reduction in weight. We furthermore feel that for the average postoperative patient the use of an appropriate diet is an indispensable part of the follow-up treatment.

Functional Disturbances. Just as the gastric acidity in cases of biliary tract disease has been in general overlooked, so has been neglected the group of functional disturbances of the biliary tract popularized by Ivy under the name of "dyskinesias." While all patients will not fit into these classifications, a brief survey of this field nevertheless seems in order.

Hypertonic Gall-Bladder with Gastric Hyperacidity

The importance of gastric hyperacidity has been previously mentioned. Clinically a nervous person, frequently with many worries, presents himself with a history of recurrent attacks of severe colic, associated with indigestion and possibly heartburn. Physical examination is usually negative. X-ray examination shows an enlarged gall-bladder shadow, with delayed emptying

recommended in every case where there is doubt as to the exact nature of the biliary tract disorder

Reliable evidence of disease can be obtained in most cases from the drainage findings by determination of the gastric acidity, gross and microscopic examination of the bile specimens, and bacteriological cultures of the bile obtained under sterile precautions. Abnormally concentrated bile indicates biliary stasis. Absence of concentrated gall-bladder bile may be found in the diseased gall-bladder, cystic duct obstruction as by a stone, or in jaundice. Abnormally dilute bile occurs in liver disorders. It is furthermore necessary to recognize that in common duct obstruction important differential diagnostic information is obtained by duodenal drainage, for the presence intermittently of some bile in the drainage is against neoplastic obstruction.

Microscopic examination of the biliary sediment as described by Lyon, gives evidence of significance in that considerable numbers of cholesterol or calcium bilirubinate crystals are frequently found in the bile of patients with stones. Bile-stained pus cells, desquamated columnar epithelial cells, or cultures of pathogenic bacteria are evidence of infection. Bile-stained mucus and pus cells are common in the catarrhal types of jaundice, cultures in these cases are usually sterile. In the postoperative patient with symptoms, common duct stones almost invariably show "sand" or calcium bilirubinate granules in the drainage bile, with *B. coli* on cultures taken with sterile technic.

Gastric Acidity Among other advantages of the biliary drainage is the opportunity of obtaining a gastric specimen. While disturbances in acidity occur in seventy-five per cent of patients with cholecystitis, its importance in producing symptoms and pathology however is seldom realized. As a matter of fact, rarely is the gastric acidity even considered in the treatment of these cases. At the same time we find repeatedly that the correction of hyperacidity entirely relieves colic in patients without stones who might otherwise come to operation. Furthermore the same treatment has been found most effective in patients with hyperacidity having colic following the removal of the gall-bladder. On the other hand gastric

achlorhydria is an important contributing factor to biliary tract infection, most patients showing positive cultures of the biliary tract at operation having no free hydrochloric acid in the gastric specimens.

Blood Chemistry Just as a urinalysis is part of our routine study, so is a *blood Wassermann*, particularly in patients with jaundice. *Blood counts* may show a marked degree of anemia in the chronic cases, or a surprising leukocytosis in acute conditions. Repeated *icterus index* tests are needed in all cases of jaundice to indicate the degree of obstruction and its variability. A *blood cholesterol* determination affords a practical guide for dietetic therapy, as a lowered cholesterol esters may indicate concomitant liver damage as demonstrated by Heyd and Graham.

Surgery

Cholelithiasis We consider biliary calculi an indication for surgical intervention. Stones lead to trauma and subsequent pathology. There is in these cases frequently infection, impairment of vascularity of the gall-bladder, and toxemia which may become severe and affect even the cardiac musculature. Small stones are frequently associated with colic. A nonfunctioning gall-bladder, as shown by lack of visualization and the absence of concentrated bile on drainage, is an indication for its removal.

Urgency for operation may be determined by the degree of physical disability of the patient, the frequency of attacks of colic, chills or fever, the failure to respond to medical treatment, the general appearance of toxemia, or the presence of recurrent jaundice. While it is in many cases possible when necessary to carry these patients on medical therapy, about forty-six per cent in our experience are not relieved of their pain. Many are forced to have emergency operations, which are attended with an increased mortality and much morbidity.

Acute Cholecystitis In passing, mention should be made that so-called acute attacks of cholecystitis are in reality acute exacerbations of a chronic cholecystitis, in most cases associated with the presence of stones. It should furthermore be kept in mind that it is possible

to have an acutely inflamed tender distended gangrenous gall-bladder, practically ready for perforation, with a normal temperature and blood count. An initial subacute attack, however, may subside and the gall-bladder return to an apparently normal condition. A careful check-up for stones is essential in these cases, after the subsidence of the acute symptoms.

Surgical Jaundice Another serious problem frequently coming to our attention is that of prolonged jaundice. The usual maximum duration of the so-called catarrhal jaundice is six weeks, any jaundice extending over this time is entitled to an immediate surgical consultation. The importance of liver damage and impaired function from prolonged obstruction cannot be overemphasized.

Among the most common causes of prolonged jaundice are common duct stones, malignancy, and pancreatitis. Probably the most accurate test for complete common duct obstruction is the absence of bile upon duodenal drainage, when the position of the tube has been checked by the fluoroscope. The relationship of the common duct stone with "sand" of calcium bilirubinate and colon organisms in the duodenal bile has been mentioned. Blood may be found with malignancies. The diagnosis in many cases must rest upon continued observations, repeated drainages, and repeated icterus index determinations.

Medical Management

General Every patient with disease of the gall-bladder should in our opinion have medical supervision, regardless of the necessity of surgical intervention. The principal reason for this statement is the number of patients referred to our clinic with severe indigestion following the removal of the gall-bladder, who have been told to "eat anything they want." Few of these patients have evidence of stone or stricture. Many are entirely relieved by a proper dietary and hygienic regime, together with such medication as may be indicated by the diagnostic work-up.

Dietary For many reasons diet seems one of the most important of all therapeutic measures in cholecystitis. Many varieties of gall-bladder disturbances do

not lend themselves equally well to the old style single type of "low fat diet." In the presence of cholelithiasis, hypercholesteremia, or active infection, the low cholesterol low fat diet is undoubtedly best. However in those patients having an enlarged atonic distended gall-bladder, in the absence of the findings previously mentioned, best results are frequently obtained with a stimulating type of diet, relatively high in fats and cholesterol. For those patients with a gastric hyperacidity, duodenitis, gastric irritability, or pylorospasm, a modified Sippy type of diet, high in carbohydrates and with intermediate feedings, gives excellent and at times dramatic results.

The importance of diet in patients treated surgically must be emphasized. The patient "afraid to eat" frequently presents himself for operation in a state of both dehydration and emaciation, a most discouraging operative risk. The essential preoperative preparation includes the forcing of fluids and the strict observance of a diet high in carbohydrate value, preferably with the addition of sugar, to build up the glycogen reserve of the liver. On the other hand the cases of extreme obesity commonly found to be in need of surgery, may be greatly benefited by a preliminary reduction in weight. We furthermore feel that for the average postoperative patient the use of an appropriate diet is an indispensable part of the follow-up treatment.

Functional Disturbances Just as the gastric acidity in cases of biliary tract disease has been in general overlooked, so has been neglected the group of functional disturbances of the biliary tract popularized by Ivy under the name of "dyskinesias." While all patients will not fit into these classifications, a brief survey of this field nevertheless seems in order.

Hypertonic Gall-Bladder with Gastric Hyperacidity

The importance of gastric hyperacidity has been previously mentioned. Clinically a nervous person, frequently with many worries, presents himself with a history of recurrent attacks of severe colic, associated with indigestion and possibly heartburn. Physical examination is usually negative. X-ray examination shows an enlarged gall-bladder shadow, with delayed emptying

The gastrointestinal series, if done, shows a pylorospasm or duodenitis, with no ulcer. Biliary tract drainage gives concentrated gall-bladder bile, possible evidence of biliary stasis, and gastric hyperacidity.

Treatment It is in this condition that a differential diagnosis is of assistance in treatment, because of the fact that in the absence of stones the results of surgery are at times unsatisfactory, whereas the medical treatment usually gives good results. The modified Sippy type of diet is in these cases supplemented by the use of alkalies to neutralize the hyperacidity, while sedatives or antispasmodics are of additional value. Repeated duodenal drainage gives remarkable symptomatic relief in many of these patients.

Hypertonic Reflex Gall-Bladder

A similar clinical picture may be presented, by patients having evidence of a reflex disturbance of the biliary tract. Due to nervousness or worry, this may originate in the central nervous system. At times however there are other apparent reflex causes, such as diseased appendix, ulcer, gall-stones, or a pyelitis. Gastric hyperacidity is usually not found in these cases.

Treatment In general the primary consideration in the treatment of these patients is the relief of the source of origin of the reflex irritability, if necessary by removal of the patient from his environment or by the correction of some abdominal pathology. The same modified Sippy type of diet gives good results, if aided by sufficient sedatives. Alkalies are not generally necessary, but antispasmodics are frequently helpful in the relief of symptoms. Duodenal drainage is at times of additional value.

Hypotonic Gall-Bladder

The enlarged flaccid gall-bladder shadow showing little tendency to empty following

the fatty meal is familiar to roentgenologists. Patients having gall-bladders of this type are usually obese, sthenic in habitus, sedentary and phlegmatic in nature. The pain of which they complain is of a dull constant character and colic is rare. In digestion is practically always present, frequently with anorexia and nausea. Diagnostic duodenal drainage shows a deficiency in gastric acidity, and a deficient response to stimulation, which are useful guides in treatment. Biliary sediment is usually suggestive of stasis or stones.

Treatment In the absence of stones, active infection or fat intolerance, these patients respond well to a stimulating type of diet, relatively high in fat and cholesterol. General hygiene is important, and regular meals with intermediate feedings tend to relieve stasis. Dilute hydrochloric acid by mouth (we use a dram in orange juice with each meal) seems to aid gall-bladder function. The use of tonics, particularly containing strychnine, is also indicated.

Conclusions

The patient with disease of the biliary tract is practically never "cured." A careful and complete initial diagnostic work-up including a good history, is essential for satisfactory treatment. A few of the definite indications for surgery, such as stones, infection, and obstruction, have been briefly discussed. Prolonged observation and medical management is desirable in all cases of biliary tract disease. In those patients suffering from functional disturbances, the diagnostic findings as described serve as a guide for the medical treatment outlined which has proved very satisfactory in our actual clinical practice.

AMERICAN COLLEGE OF PHYSICIANS

The Twenty-second Annual Session of the American College of Physicians will be held in New York City, with headquarters at the Waldorf-Astoria Hotel, April 4-8 1938.

Dr James H. Means, of Boston, is President of the College, and will have charge of the program of general scientific ses-

sions. Dr James Alex. Miller, of New York City, has been appointed General Chairman of the Session, and will be in charge of the program of clinics and demonstrations in the hospitals and medical schools and of the program of Round Table Discussions which are to be conducted at headquarters.

METHODS OF ADMISSION AND DISCHARGE IN NEW YORK STATE HOSPITALS

BENJAMIN POLLACK, M D, *Rochester*

*Senior Assistant Physician, State of New York Department of Mental Hygiene,
Rochester State Hospital*

While methods for admission and discharge in New York State Hospitals for the mentally ill are relatively simple, they nevertheless, still continue to be a source of great difficulty to most physicians. As a result there is frequently delay in admitting these patients because of improperly completed formal papers. It is with the hope of simplifying this situation that this article is written.

Methods of Admission

Any person who is believed to be mentally ill to such an extent that institutional care is necessary and who is not being held on a criminal charge, can be admitted and confined to a State Hospital or Psychopathic Hospital, or to a licensed institution. The methods of admission are

- 1 On voluntary application
- 2 On a Health Officer's Certificate
- 3 On certificate of one Physician
- 4 Court or regular commitment.
- 5 An incomplete court commitment or emergency commitment.
- 6 Criminal order
- 7 Order of transfer
- 8 By special agreement for residents

On Voluntary Application Patients may be received and confined when they voluntarily make written application on a special form prescribed by the Commissioner of Mental Hygiene. (41 Medical) These patients must be suitable for care and treatment in a mental hospital. They must have therefore, a certain degree of insight into the fact that they are mentally ill. They must also be 21 years of age and acceptable to the superintendent of the institution. Minors may be admitted when the voluntary application is completed by a guardian or parent or next of kin.

Patients of this type must agree to abide by the rules and regulations of the hospital. They may leave the hospital at any time by a written notice of this fact

to the superintendent. However, the superintendent may keep the patient in the hospital for an additional ten days after notice is given but no longer. This provision is necessary because occasionally such patients are found to be dangerous to themselves or to the community and this time interval affords a necessary period wherein the relatives may be communicated with and advised of this fact. Should the relatives desire, they can then have the patient formally committed on a regular court order. However, should they not desire to do so, the patient must be released ten days after and inclusive of the date when the notice is given in writing.

Certificate of a Health Officer The superintendent of a state hospital, or a licensed physician, may receive a patient for care and treatment when requested by a health officer. This provision, however, relates only to patients who require care for some mental abnormality other than drug addicts or drunkards. A special form (818 D M H) is prescribed which must be completed by the health officer.

A patient who is deemed unsuitable for treatment under this type of commitment must be removed from the hospital by a Public Welfare Officer of the district from which the patient came, or by the patient's relatives. They, however, may have the patient committed by a regular court commitment should the patient be found insane. It must be stressed however, that a Health Officer's certificate is good only for thirty days following which the patient must either be discharged or be committed on a regular court commitment. The expenses of this commitment can be ascertained by the judge ordering the commitment and will be a charge upon the town or district, or the patient's relatives.

While this form is frequently used to commit patients in emergencies, it is nevertheless, a poor method since it has been abused to such a great extent. It

takes little more time to have a patient committed in the regular fashion at the beginning and saves the expense of later on sending two qualified examiners to the hospital to examine the patient and then proceeding with the regular commitment. Emergencies seldom arise where it is necessary to use this form, except in districts where it is difficult to obtain the services of two qualified examiners. A much better form to use in cases of emergency is an incomplete court commitment which will be dealt with later on.

Certificate of One Physician This form is little used now. However, patients may be received on this form which consists of a certificate completed by a qualified examiner on form 92 D M H, and dated not more than ten days before the admission of the patient to the hospital. This form, again, may be of only temporary value since the patient cannot be detained more than thirty days after he, or any person on his behalf, makes a written request for his release. But, should the superintendent or judge believe that such confinement is necessary, he may so certify to a judge of a court of record who may then issue an order committing such patients for indefinite care, custody, and treatment.

Court of Regular Commitment By far the largest number of patients are admitted by this means. This special form (472) consists of three essential portions—(a) petition, (b) examination by two qualified examiners, and (c) order of commitment signed by a judge.

In addition to these divisions there are also included two other measures for service of notice and for a court hearing if such be demanded. The petition consists of an application for an order of commitment stating the facts upon which the allegation of mental illness is based. Only definite individuals may act as petitioner. These comprise

Any person with whom the alleged person may reside or, at whose house he may be or, father or mother, husband or wife, brother or sister, or the child of any such person, or the nearest relative or friend available, or the committee of such a person, or an officer of any well recognized charitable institution, agency or home, or any public welfare officer of the town, or the commissioner of public welfare of the city or county in which any such person may be

Medical Examination This consists of an examination by two qualified examiners. A qualified examiner in the meaning of the law is

A reputable physician who is a graduate of an incorporated medical college, duly licensed to practice medicine in this state, who shall have been in actual practice of his profession for at least three years at the time of the certification as such by a judge of a court of record in the form prescribed by the commissioner.

The original certificate is filed by the clerk of the County in which the physician resides, and the certified copy which is duly acknowledged is filed and recorded in the office of the Department of Mental Hygiene. Following this acknowledgment, the physician is a duly certified medical examiner in lunacy or mental defects, and the name added to a list of all qualified examiners and psychologists, published by the department.

No qualified examiner may be a relative of the person applying for admission or have any pecuniary interest, directly or indirectly, or be a resident physician in the institution at which it is proposed to admit such a person. Notice of application must be served personally at least one day before making such application upon the person alleged to be mentally deranged except if the judge to whom such application is made is satisfied from statements contained in the papers or from inquiry that personal service of the notice on the alleged person would be ineffective or detrimental to such a person. He may at his discretion dispense with it if the qualified examiners state in writing, under oath, that personal service upon the alleged insane person would in their opinion be detrimental to such a person. However should a petition be made by a person other than a husband, wife, father, mother or other nearest relative, such notice shall be served upon them if they are known to be within the county and, if not, upon the person with whom the alleged mentally ill patients may reside or at whose house they may be, or in their absence, upon a friend of such a person. If there are none such, service may be dispensed with in writing.

The joint examination of the two physicians must be made at least within ten days (not longer) before the issuance of

the formal order by the judge. Likewise, the patient must be sent to a hospital or institution within ten days after the order is issued by the judge. This provision was made in order that relatives of the patient would not be able to hold the commitment as a whip over the head of the committed person in order to attempt to force him to good behavior.

Formal Order of Commitment The judge to whom such application is made, after being satisfied that the person is mentally deranged, may immediately issue an order for commitment of such a person to a proper institution for custody and treatment, provided that no hearing is demanded on the patient's behalf. Upon this demand by a relative or friend, the judge may issue an order directing the hearing before him at a time not more than five days from the date of such an order and it shall be served upon all interested parties whom the judge may, at his discretion, name.

After such a hearing, the judge may issue his order of commitment or may refuse to issue such an order, the reasons for which he must state in writing on the certificate under his signature. When the commitment is made to a state hospital, the judge will issue a statement, also in writing, regarding the financial condition of the patient and name the persons legally liable for his maintenance, if these can be determined.

The superintendent or person in charge of an institution may refuse to receive such an individual upon such an order if the accompanying papers do not comply with the regulations of these sections of the mental hygiene law (Article 5, Sections 70 to 72 of the laws as stated by Chapter 395, laws of 1933), or, if in his opinion, such a person is not mentally deranged within the meaning of the Statute. No person will be received at such an institution under such an order after the expiration of ten days from and inclusive of the date of the order.

Incomplete Court or Emergency Commitment In spite of the requirements of section 74, providing for a court order, there is a special provision in cases where it would be for their benefit to receive immediate care and treatment when they are dangerously insane, or there is no other proper place available for this care.

Such a person may be confined immediately upon the receipt by such an institution, of the usual petition and examination by two qualified examiners and may be retained in such an institution for a period not to exceed ten days from and inclusive of the date of the certificate. Such forms (472 DMH) should be executed in duplicate, one form to accompany the patient and another to be sent to the judge who, at his discretion, may issue the formal court order, completing the certificate before the ten day period elapses. On the form accompanying the patient to the institution, adequate reasons must be given for the individual to require immediate care.

If a person committed to an institution, or a relative of friend, be dissatisfied with the order, he may within thirty days after such an order, obtain a re-hearing and review of the proceedings already had and of the order of commitment upon petition to a justice of the supreme court, other than the justice making the original order of commitment. A jury may then be summoned to investigate the question of facts arising on the competency of the person and the question of his commitment, and depending upon the verdict of the jury, the justice shall either discharge him or certify an order of recommitment.

The costs necessarily incurred in determining the question of mental derangement of a poor or indigent person is determined by the judge or justice ordering the commitment and is a charge upon the town, city or county, except in the city of New York. Here it may be allowed in the first instance by the judge who designated the qualified examiners or by the comptroller of that city, and will be paid by the chamberlain on a warrant of the comptroller from the court funds and charged to the proper county within the city.

If the person is not a poor or indigent person the expenses may be collected from the estate of such a person or from persons liable for their maintenance. The father, mother, husband, wife and children of such a person, if found to be of sufficient ability, or the committee or guardian of his person and estate, if sufficient for this purpose, are responsible for the care and maintenance of the patient.

During the period prior to commitment

to a state hospital, it is incumbent upon the health officer or commissioner of public welfare to provide a suitable place for their detention in the case of indigent persons. This may not consist of the ordinary jail cell but must be in a suitably constructed room such as the hospital ward of the prison or any general hospital, or special room where proper care and treatment and nursing are provided pending the determination of his mental condition and possible commitment. In the case of indigent patients, the public welfare officers must also provide proper and adequate clothing to the patient and this is a charge upon the village, city or town.

Other Methods of Admission

(1) *Special agreement* The commissioner of mental hygiene may authorize the superintendent of the hospital to admit under special agreement mentally deranged patients who are residents of New York State. However, no patient is allowed to occupy more than one room in any state hospital. All patients are subject to the same rules and regulations.

(2) *Order of Transfer* When a patient is confined to one state hospital and the relatives or friends should so desire, they may have him removed to another state hospital. The commissioner of mental hygiene may issue such an order of transfer if the superintendent is willing to accept this transfer.

(3) *Criminal Order* If a person not held for a felony, is confined under a criminal charge or for want of bail for good behavior, or for keeping the peace, or for appearing as a witness, or by order of any magistrate, or under any other than civil process, shall appear to be mentally deranged, the justice or magistrate having jurisdiction over the city or county in which this individual resides, may commit such a person to a state hospital within the district after the superintendent or person in charge has consented to receive such a patient. The superintendent, after a suitable period of time, will make a report to the court stating the conclusion reached and return the patient to the custody of the sheriff.

When a patient is charged with the commission of a felony or is held for

action of the grand jury the judge may also, as an aid in determining whether the individual is of sound mind, commit him to a hospital for observation for a reasonable length of time and direct that a report be made by the superintendent of the hospital. Should the person be found to be mentally deranged, the judge may discharge the criminal action and commit him to the Matteawan State Hospital for the criminal insane until restored to his right mind. He is then turned over to the sheriff for trial of his criminal action. If found to be sane in his original commitment for observation at a state hospital, the patient is turned over to the custody of the sheriff to stand trial for his criminal act.

The judge, at his discretion under a recent law, may appoint a committee of three to further investigate the question of the patient's mentality if requested by the patient or, if satisfied with the opinion of the superintendent of the state hospital, he may then proceed to summary trial of the prisoner.

Discharge of Patients

While it is generally recognized that many patients are sent to state hospitals—the present population in the Civil New York State Hospitals up to February 1, 1937, was 63,891—it is not so clearly known that numerous patients are also paroled or discharged from these hospitals. Some of these may be able to adjust indefinitely while others may and will require at varying intervals, further institutional care. Associated with the paroles of patients are also specialized agencies, the social service, and the clinics conducted by the hospitals for further guidance of the patients and investigation of special problems. At the present time the number of patients on parole amounts to approximately 6,000.

The superintendent or physician in charge of a state hospital, may discharge any patient except one held upon the order of the court or judge having criminal jurisdiction in action or proceedings arising out of a criminal offense. A patient may be discharged, who in the superintendent's judgment is

(1) Recovered (2) Not recovered, but whose discharge will not be detrimental to the public welfare or injurious to the pa-

tient (3) One who is a dotard and not insane

The superintendant may refuse to discharge any patient whose discharge, in his judgment, would be detrimental to the public welfare or injurious to the patient

Methods by which patients may be discharged from state hospitals comprise the following

- (1) Parole.
- (2) Not insane
- (3) Habeas Corpus
- (4) Non-resident.
- (5) Death
- (6) Elopement or escape
- (7) Order of transfer
- (8) Immediate discharge without parole.

Parole Suitable patients may be granted a parole not exceeding one year, during which time the individual may be returned to the hospital should his conduct turn out to be unsatisfactory. Such patients, if without means, must be provided with the proper clothing, and following this the commissioner of public welfare becomes responsible for their further needs. Following expiration of one year parole the patient may then be discharged. As a rule, patients while on parole, are required to attend a mental hygiene clinic held at various convenient locations by the members of the staff of the hospital, where an attempt is made to help the patient adjust himself adequately to an outside environment

Not Insane If, after a suitable examination, a superintendent determines that the patient is not insane or has recovered, he may be forthwith discharged from the custody of the hospital

Habeas Corpus In order to protect the personal rights of the patient, provision has been made in the law, whereby any patient who believes himself to be improperly detained in a state hospital, may ask for Habeas Corpus to determine the question of his mental derangement. Should such an order be granted and the

patient found to be mentally sound, he may then be discharged by a court order of the presiding judge

Non-resident A person who has not gained residency of the state may, if non-residency be established, be deported to the state or country in which he is a resident

Death A patient will, of course, be discharged from the state hospital records should he die while a patient there

Elopement or Escape Should a patient escape from a hospital and not be discovered after vigorous measures are taken to secure his return, he must be discharged if not returned before the expiration of one year and if discovered later he must be readmitted only upon a new order of commitment. However, a patient held on a criminal order or warrant of arrest by the United States Government as preliminary to deportation must be, upon apprehension, readmitted to such an institution on the original order of commitment.

Order of Transfer A patient may be discharged from one state hospital by transfer to another hospital following the receipt of an order of transfer from the department of mental hygiene

Summary

The methods for admission and parole of patients to state hospitals have been outlined. All the necessary forms can be obtained upon application to a state hospital or to the Department of Mental Hygiene. As can be seen the methods are relatively simple but, nevertheless, still appear to be in a state of confusion in the minds of a great many general practitioners who resort to commitment of patients infrequently. It is hoped that this brief outline will be of some help in guiding them to an understanding of the proper procedures available

STATE HOSPITAL

Prospective mothers are like athletes in training for an important event. They should live according to the rules to assure a well baby and a healthy mother. Approved diet contains nourishment for the mother and materials for building the body of the baby. Starches, fats, vitamins and minerals, with plenty of milk, leafy vege-

tables, whole wheat bread and restricted amounts of meat are recommendations often made. Women who are to be properly prepared for motherhood should have the care and advice of a physician throughout the period, and for several weeks after

SOME PROBLEMS IN HEAD INJURIES

FRANZ SCHUCK, M D, *New York City*

Neurosurgeon, Queens General Hospital, New York Former Professor of Surgery, University of Berlin, and Director of the Municipal Hospital am Urban, Berlin

When choosing a practical topic like head injuries, I should first report to what material I am referring. It consists of war injuries treated at the German front from 1914 to 1918, of the post-war material in the surgical hospital of the Charité, the former Royal Hospital in Berlin, and of the patients treated in the Urban Krankenhaus Hospital in Berlin from 1925 to 1933.

Exact figures are not available from the war material, and difficult to obtain from the different wards in the Charité, while from the surgical department of the Urban Krankenhaus we published about one thousand cases of head injuries during my activity there.

Since our discussion will deal mostly with peacetime accidents, I refer mainly to the cases treated in the Municipal Hospital am Urban. They are probably very similar to yours, since the Urban Hospital in Berlin covered the section with the heaviest traffic.

When speaking of the problems of head injuries, one could follow two points of view both of which may be considered. The first is the practical problem of treatment which, in order to compare American with European methods, should be summarized as concisely as possible, the second—the real problems of an injured brain, some of which I will touch upon hereafter.

Let me begin with a simple question which, as in injuries of the spine, is practically the most important.

Which cases have to be operated upon?

In answering this question, we should not confine ourselves to the conditions of a specialized department of high standards (as the neurological department of Bellevue Hospital). We should try to formulate our indications as simply and precisely as possible, so that they may be useful to smaller hospitals with a less specialized staff, since they actually have to handle the street accidents all over the

country. A similar simplification was desirable in my former activity, because in the Municipal Hospitals of Berlin, these head injuries were treated by the general surgical departments.

In this interest of simplification, we may divide the operative indications into two general groups.

First, cases in which wounds need surgical treatment from merely surgical considerations, and

Second, cases which have to be operated from neurological and neurosurgical viewpoints.

The first group—the open injuries—regardless of whether they pertain to skin, bone, or even brain, are submitted to exactly the same surgical rules as all other regions of the body. The danger is the infection and the treatment is identical with that of other infected wounds and of compound fractures. It is true that the right middle course, not to be too conservative in order to check the infection, and not to be unnecessarily radical in order to spare brain and bone, that this middle course is a matter of experience, but it does not differ from the surgical rules in other regions of the body.

Perhaps I may mention one special experience which, I imagine, you also had during the war and in accidents of peacetime—that one should never give up a compound fracture of the skull on account of its hopeless outer aspect, and that one should not be discouraged by large openings of the bone or by crushed brain lying upon the skull. Bad as those cases look, they occasionally have a surprisingly good outcome. And in the experience of the old military surgeons, which is recorded in wound books of the fifteenth and sixteenth centuries, there is a considerable degree of truth, namely, that a large hole in the skull is often less dangerous than a simple, as they call it, "concussion."

But let us leave these cases with open wounds which have to be treated from

merely surgical standpoints. Then the great majority remains, the treatment of which depends on special conditions of the brain. And these cases represent the actual problem of treatment.

There are three operative indications, and one of them is by far the most important—increased intracranial pressure by bleeding of an intracranial vessel.

I do not need to discuss the clinical symptoms with this audience. But perhaps you may be interested in a sketch (see illustration) with which, in the interest of the aforementioned simplification, I used to explain the diagnosis in teaching.

I said "Here you have the concussion with its typical course. Here is the moment of the accident. And the symptoms, including the lack of consciousness decrease continuously."

"Contrariwise, you have the course of the intracranial bleeding. Here is the accident. After the accident, theoretically nothing but the symptoms continuously increasing, until, theoretically, death."

"Now in most cases these curves are combined. After the accident, you have the symptoms of the concussion, and they decrease typically. But, from a certain moment on, they go over into the symptoms of the compression, and the main thing is not to overlook this point X."

It is obvious that the general condition alone is not characteristic of brain pressure. But it is characteristic along with the second symptom—change of pulse.

As to the pulse, it is not characteristic in concussion. There it may be slowed or accelerated, but just as well, it may be rather normal, even in a severe state of concussion. And the same inconstancy is found in the cases of increased brain pressure by a growing tumor.

But the pulse is characteristic and reliable, slow and full, in those cases of traumatic intracranial bleeding, in which within a few hours or a day, an injured vessel causes an increase of pressure. So the course alone is not decisive and the pulse alone is not decisive, but together these two symptoms are almost infallible in answering the vital question, "Increasing brain pressure or not?" That means, *operating or not?*

It is true that such cases of a real increasing brain pressure by an increasing intracranial bleeding are relatively few in

the entire number of head injuries (I think, in my former material of peacetime, not more than three to five per cent at the most). But they represent the group in which the patient is lost without operation and saved by operation. And therefore they must be recognized by every physician.

In addition to this most important indication, there are two others of minor difficulty. The first are the cases with a simple *depressed fracture* of the skull. It

has often been discussed in which cases these depressed fractures should be operated upon and in which not. I think this question is unnecessary. Provided the asepsis is reliable, I should always operate on depressed fractures if the general condition of the patient permits it.

The second situation is presented by focal symptoms of the cortex without visible depression of the bone. There are generally two possibilities—shattering of the lamina vitrea or compression of the cortex by a localized hematoma. But these decisions are not so vitally urgent and

therefore can be delayed for observation and, even in small hospitals, for neurological consultation

Hence we acknowledged three operative indications in the primary stage of a head injury, first of all, increase of brain pressure by increasing intracranial bleeding, second, all depressed fractures of the vault, and third, with the aforementioned reserve, focal symptoms of the cortex

I stressed the point of the increasing brain pressure because, in Germany, the attention of the physicians was frequently directed towards other considerations which, in this primary stage, are much less important

Such a problem of minor primary importance is the question of a *fracture of the skull*. Linear fractures of the skull have no influence upon the treatment within the first three days. This is well known of the *fissures of the vault*. They are found since the development of the x-ray technic, while they were not found before. In our experience they have no clinical importance. This is proven by cases in which the fissure is found accidentally. For instance, two men were admitted to the ward the same night, both somewhat intoxicated. One of them with a sprained ankle, the other with a slight injury of the head. X-rays were ordered for both. But by a mistake, the nurse confused the names. And to our surprise the man with the sprained ankle had an accessory fissure of the vault. Since he had no discomfort at all, it was rather difficult to keep him in the hospital the next morning.

But the *fractures of the base* are considered much more serious and, in fact, they are. But their clinical importance consists of a fact which does not appear before the third day after the injury—the danger of secondary infection through the opening of the accessory mucous cavities. Within the first two days, danger is not represented by the fracture of the bone, but by the parallel injury of the basal brain. The same physical lines of force which cause the bursting of the basal bone, are responsible for the injury of the basal brain. The result is a more or less severe injury of the brainstem with or without hemorrhage and contusions.

With this conception of the fracture of the base I necessarily desisted from operating on basal fractures unless, as mentioned before, there was a markedly increasing brain pressure, independent of the diagnosis of basal fracture. In pursuing the postmortem examinations of basal fractures for about fifteen years, I have seen *extremely few cases in which an operation would have saved the patient*. Contrariwise, I saw many cases in which the surgical decompression, correctly performed on account of diagnosed brain pressure, could not save the life of a patient with basic fracture because, in addition to the hemorrhage, his brainstem was fatally injured.

Through this, I think we are entitled to limit the operative indication to the general consideration of brain pressure without making any special conditions for the fracture.

After having indicated some outlines of therapy as concisely as possible, perhaps I may enter into some real problems of brain injuries which are fundamental for the future development of treatment. An old classical problem which occupied general surgery long before there was any neurosurgery is the *mechanism of the trauma*.

The best monograph about the mechanism of head injuries is still the classical work of Kocher published in 1900. One of his main experimental collaborators was Dr. Cushing, at that time in the surgical hospital in Bern. Kocher's work was named "Concussion of the Brain, Compression of the Brain and Surgical Operations in Diseases of the Brain."

While the chapter about operations is rudimentary (1900) Kocher's investigation of the mechanism is classical and, I think, will remain fundamental.

When speaking of the concussion of the brain, or, in the German language, the "*Hirnerschütterung*," Kocher always uses the term, the "so-called" concussion. By this he denied the conception of a vibration which is contained in the word concussion and particularly in the German word "*Erschütterung*." In a blunt head injury, Kocher acknowledged only one mechanical happening—the compression. For him the concussion of the brain is an acute compression of the brain tissue. So he only differentiates between

an acute and chronic compression of the brain tissue

I shall not take up your time by a detailed description of the classical experiments of Kocher and his school, nor shall I tire you by a report of my own experiments performed fifteen years later in the Charte, which convinced me of similar happenings in the brainstem. I had better mention the fact that outstanding physicists whom we consulted on this question approved the mechanical factor of the compression and denied any other physical happening. In 1920, Dr. Einstein, at that time in the Kaiser Wilhelm's Institute in Berlin, was kind enough to help me in this matter by sending Dr. Reiche, his associate, and this scientist, without touching upon any physiological or medical question, confirmed the physical conception of the acute compression.

When speaking of the acute compression, I have to report the following. In 1913 I published the theory that concussion of the brain was caused by an acute compression of the lower brainstem and represented its symptoms. This theory was rather courageous when published mainly from laboratory observations and by a young physician with a very limited experience. But strange as it is, after twenty years of practical experience with head injuries, I still believe the theory was correct.

In order to prove this conviction, I should go into details which I am afraid would take up your time with too much theory. But I shall be glad to furnish proofs in case you are interested.

Not to be misunderstood, this does not mean any doubt of Hitzig's classical theory that consciousness is composed of actions which are localized in the entire brain cortex. This classical theory of the cortex has been modernized and, if I may say so, greatly improved by Dr. Kennedy's conception of the multiple, specific centers all over the cortex. But the fact that consciousness is based upon activity of the brain cortex does not mean that there are not close connections with the brainstem, and particularly does not mean that it cannot be interrupted from the brainstem. And I think there is overwhelming clinical material to prove that this actually happens in severe head injuries.

When continuously speaking of brain injuries, we should consider what actually happens to the brain tissue. But this is not easy to summarize.

Again, we may start from the experimental observation that an animal goes into a bad coma or dies when its lower brainstem, particularly the rhomboid fossa, is ungently touched. All surgeons in our midst will agree that unfortunately the human brain does not differ in this respect. Touching the rhomboid fossa, moving the organs in the basal region of the posterior fossa, or even quick change of its intracranial pressure, represent a fatal danger we try to avoid.

So, from these least mechanical injuries which may be fatal yet not visible postmortem, we have all degrees of transition to grave contusions and destructive hemorrhages within the brain tissue. In a mechanical sense, these differences are easy to understand. They were roughly interpreted by the old classical experiments of the "Coup" and "Contrecoup," and are very precisely explained through modern physical analysis. In the aforementioned collaboration with physicists, there was a remarkable conformity between their drawings of lines of force, constructed only from the detailed history of the accident, and the postmortem findings of contusions and hemorrhages in different parts of the brain. These comparisons were made with the help of our pathologist, Geheimrat Lubarsch, who, of course, had not seen the drawings before the autopsy.

While this is clear, I wish to ask one question (which Dr. Stevenson may be better able to answer than the pathologist.) I mean about the explanation of the *punctiform bleedings* all over the brain—we called them *ecchymoses*—which have so often been described as a typical postmortem finding in concussion of the brain. I wonder whether or not these findings are similar to the *punctiform bleedings* which are typically found in cases of suffocation. This would be quite understandable, since the primary death in a brain injury mostly occurs from a paralysis of the respiratory center and therefore from true suffocation. I ask this question because these hemorrhages are frequently used as a proof for the cortical theory of concussion.

But, as mentioned, these postmortem findings are generally not difficult to interpret. Much more difficult to interpret are the injuries which, probably with very little morphological effect, have taken place in a surviving brain. If they happen to be in a center with obvious symptoms as, for instance, in the vagus center, they can easily be understood as symptoms of irritation and paralysis. But we are completely helpless in regard to the many centers which we have not even started to know.

The most trying phenomena of this kind are the secondary disturbances referring to character, mood, temperament, and so forth. Fifteen years ago such a decision was easy. Whatever we could not explain with very mechanical reasons, as increased brain pressure, adhesions, irritation of well-known gyri, and so forth, was considered as a "functional" disturbance which, in our true opinion, was very closely connected with lack of self-discipline or with a more or less conscious wish for financial compensation.

In fact, this medical scepticism toward functional residua of head injuries is largely backed by the great experience of war injuries. At least this was so in Germany. We had overwhelming proof by the statistics of the German wounded that the degree of functional residua bore a direct relation to the personal interests of the patients.

It is a very similar thing in the accidents of peacetime. We saw types of vocations which had an almost complete lack of secondary complaints, such as officers of cavalry, ace flyers of the war, famous racing men, regardless whether horseback riders or automobilists, and so forth. Contrariwise, there were classes with a decidedly bad prognosis, for instance the working class, particularly in periods of a liberal insurance legislation.

Hence it is only logical that we retain our scepticism and are suspicious towards everything which seems to exceed the normal. To give a rough outline—in compensation cases without apparent anatomical change, we were usually very liberal during the first year, less liberal during the second, and illiberal after two years.

However, there is some very uncomfortable feeling connected with this at-

titude. There is no doubt that this empirical and rather rough judgment corresponds in no means with the present stage of pathological and clinical brain investigation. In a time in which, even in general medicine, functional disturbances are going to be transmuted into very material happenings of a chemical, electrolytic, and hormonal nature, one feels rather uneasy in neglecting organs which, as the hyperthalamus, are regulating centers of these happenings.

Undoubtedly, future laboratory work will contribute more and more to a change in the merely empirical judgment of these compensation cases.

Let me finish with a similar consideration for the future of brain surgery. Through Harvey Cushing, modern brain surgery has reached a climax which is comparable only to the classical rise of abdominal surgery through Billroth and his school. And likewise comparable with that period is the climax of confidence which brain surgery receives from the field of medicine.

But there is another point of comparison. Like abdominal surgery at that time, modern brain surgery is still in the early stage of an entirely mechanical conception. But history of surgery has shown that such mechanical periods are unavoidably followed by a conservative reaction and by waves of other methods of treatment and investigation. In order to overcome this dangerous reaction, brain surgery should control its own activity, should become neither one-sided mechanical nor too aggressive, in spite of the temptations of a brilliant technique. From this standpoint, I fully sympathize with the surgical principles in the neurological department of Bellevue Hospital where ideas are radical and action conservative.

In this case, but in this case only, brain surgery will increase its present distinction when the development of brain research enters other and less mechanical fields.

This change of endeavors has been particularly impressive to me through the course of my medical life.

I started in the orthodox Swiss school of Kocher and Hildebrand, which, in spite of its singular familiarity with the brain, worked with an almost mute brain-

stem. And after twenty years of practical work, I meet this same brainstem in your laboratory, but alive with new autonomous, chemical, and hormonal problems, moreover with problems which allow new ways for endeavors in neurosurgery.

So I wish to close with sincere thanks to the men of the Neurological department of Bellevue Hospital, who, through their knowledge and friendship, helped me to resume work in this old, familiar, but greatly altered field.

Case Report

THEVETIN IN POSTOPERATIVE THYROID CRISIS AND COMPLICATING BRONCHOPNEUMONIA

L W GORHAM, M D, S J MARTIN, M D, C C NUCKOLS, M D,
and J C MCCLINTOCK, M D, *Albany*

From the Departments of Medicine and Physiology Albany Medical College

Current literature has established the pharmacological activity of thevetin, a cardiac glucoside, which has digitalis-like properties^{1, 2} and has emphasized its clinical usefulness in cardiac decompensation.^{3, 4} Recently, its administration has been suggested as a prophylactic measure by decreasing cardiac hyperactivity in the pre- and postoperative stages of thyrotoxicosis as well as during operative procedure.⁵ The following case is reported to show the successful use of thevetin in postoperative crisis complicated by a bronchopneumonia in which it was hoped essentially to obtain subjective relief from disturbing tachycardia and restoration of a decompensating heart.

Case Report

D R., age twenty-three, single, white female entered a local hospital on January 2, 1937, because of her complaint of "tiredness and beginning nervousness." Onset of complaint dated to its insidious appearance a few years ago. She had had a goiter for the past ten years. Since November 1936, the patient had experienced increasing nervousness, marked fatigue, palpitation, and an unusually good appetite. There was no weight loss. Past medical, social, and family history were essentially irrelevant. After three weeks' preparation with compound solution of iodine, a right thyroid lobectomy was done. On the fourth postoperative day, she left the hospital against the advice of the staff and was admitted to the Albany Hospital on the service of George E. Beilby, M D, to whom the authors are indebted for permission to present this case.

Physical examination revealed a fairly well-nourished white female apparently not acutely ill, although the face was pale and lips and nailbeds slightly cyanotic. The skin was warm and moist. Other pertinent findings were as follows:

The neck presented a surgical dressing under which there was a recent low collar incision with a small opening in its center from which a small amount of serum drained. The left and median lobes of the thyroid gland were palpable and diffusely enlarged. Examination of the larynx revealed apparently a complete paralysis of the abductor muscle on the right side. The right cord was fixed in the midline. There was a partial aphonia and a non-productive cough. Examination of the lung area revealed normal findings. The heart beat was strong and regular with a rate of 120, heart size apparently within normal limits to percussion, no murmurs heard. Blood pressure was 130/70. Reflexes were bilaterally equal and hyperactive. On admission, temperature was 99.6°F, pulse rate 120, respiratory rate 23. Laboratory examination revealed a B M R of +47, Hb seventy-five per cent, rbc 4,170,000, and wbc 10,900. Urinalysis and Wassermann tests were negative.

Further surgery was decided upon and the patient accordingly given the usual preoperative management for the next eleven days consisting of bed rest, high caloric diet, Lugol's solution, ten minims tid with sedatives as necessary for sleep. The temperature, pulse, and respiratory rates before the second operation were 100°F, 120, and twenty respectively. A subtotal resection of the left and median lobes of the thyroid gland was then done. The postoperative course was stormy with all evidences of an unfavorable prognosis. The patient com-

But, as mentioned, these postmortem findings are generally not difficult to interpret. Much more difficult to interpret are the injuries which, probably with very little morphological effect, have taken place in a surviving brain. Case Report

D R., age twenty-three, single, white female entered a local hospital on January 2, 1937, because of her complaint of "tiredness and beginning nervousness." Onset of complaint dated to its insidious appearance a few years ago. She had had a goiter for the past ten years. Since November 1936, the patient had experienced increasing nervousness, marked fatigue, palpitation, and an unusually good appetite. There was no weight loss. Past medical, social, and family history were essentially irrelevant. After three weeks' preparation with compound solution of iodine, a right thyroid lobectomy was done. On the fourth postoperative day, she left the hospital against the advice of the staff and was admitted to the Albany Hospital on the service of George E. Beilby, M D, to whom the authors are indebted for permission to present this case.

Physical examination revealed a fairly well-nourished white female apparently not acutely ill, although the face was pale and lips and nailbeds slightly cyanotic. The skin was warm and moist. Other pertinent findings were as follows:

The neck presented a surgical dressing under which there was a recent low collar incision with a small opening in its center from which a small amount of serum drained. The left and median lobes of the thyroid gland were palpable and diffusely enlarged. Examination of the larynx revealed apparently a complete paralysis of the abductor muscle on the right side. The right cord was fixed in the midline. There was a partial aphonia and a non-productive cough. Examination of the lung area revealed normal findings. The heart beat was strong and regular with a rate of 120, heart size apparently within normal limits to percussion, no murmurs heard. Blood pressure was 130/70. Reflexes were bilaterally equal and hyperactive. On admission, temperature was 99.6°F, pulse rate 120, respiratory rate 23. Laboratory examination revealed a BMR of +47, Hb seventy-five per cent, rbc 4,170,000, and wbc 10,900. Urinalysis and Wassermann tests were negative.

Further surgery was decided upon and the patient accordingly given the usual pre-operative management for the next eleven days, consisting of bed rest, high caloric diet, Lugol's solution, ten minims tid with sedatives as necessary for sleep. The temperature, pulse and respiratory rates before the second operation were 100°F, 120, and twenty respectively. A subtotal resection of the left and median lobes of the thyroid gland was then done. The postoperative course was stormy with all evidences of an unfavorable prognosis. The patient com-

plained of increasing palpitation, shortness of breath, and productive cough. On the third postoperative day, the body temperature rose gradually to 102, and the following day to 103°F, with evidence of cyanosis of the nailbeds, slight dyspnea, and an irregular pulse rate averaging 160. Further examination showed a beginning bronchopneumonia and signs of congestive heart failure, edema at the lung bases, and swelling of the ankles. An EKG revealed an acute simple tachycardia, and an x-ray plate of the chest an early bilateral bronchopneumonia with a small amount of effusion at the left base. Total white blood cell count was 18,000 cu mm.

The postoperative treatment consisted essentially of the following. *First postoperative day*, 1000 cc of five per cent glucose in normal saline intravenously, sodium iodide, one gram intravenously, Lugol's solution 0.6 cc tid per os and codeine sulphate, 60 mgm for pain prn q 4 h. *Second and third days*, only the Lugol's solution and codeine sulphate were administered. *Fourth day*, after definite evidence of complication was obtained, the patient received 4300 cc of five per cent glucose in normal saline and sodium iodide, one gram intravenously in twelve hours and digitalis 180 mgm orally. Since the action of thevetin is more prompt than that of digitalis,⁴ thevetin* was administered, and served both to reduce the disturbing tachycardia and the cardiac insufficiency.

One ampoule (3 cat units) of thevetin was injected intravenously for three doses (4, 9, and 12 P M) on the fourth postoperative day. Four hours after the third dose the pulse rate dropped from 166 to 130.

*We are indebted to Dr K. K. Chen, Director of Pharmacological Research, Eli Lilly and Company, Indianapolis, Ind., who furnished us with an ample supply of thevetin.

respiratory rate from 30 to 23, and body temperature from 103.8 to 99.8°F. The urinary output, after thevetin administration was begun, increased from thirty-four to seventy per cent of the total fluid intake. Marked subjective as well as objective improvement was noted. On the following day, the TPR rose to an average of 100.6-140-26 and the dosage of thevetin was repeated three times at four-hour intervals. On the sixth postoperative day, with an average of TPR of 99-120-23, thevetin was discontinued and digitalis, sixty mgm bid was substituted for continued cardiac support. This was discontinued the next day and the subsequent course was essentially uneventful. The patient left the hospital seventeen days postoperatively, convalescent from her bronchopneumonia, with restored cardiac function, and relief from her symptoms of nervousness and fatigability. A pathological report of the thyroid gland noted a moderate hyperplasia developing apparently on a basis of colloid goiter.

The recent contribution⁷ in the prophylactic use of thevetin must be given consideration in the treatment of thyrotoxicosis. We add our experience of the efficacy of thevetin in thyroid crisis characterized by acute simple tachycardia and cardiac decompensation with complicating broncho-pneumonia.

FUTURE FORCES TO NEUTRALIZE BIRTH CONTROL

It is altogether probable that as highly efficient biologic methods of birth control are introduced, supplanting the crude devices of today, the population will nevertheless tend to be balanced by reason of very great progress in the control of such ailments as cancer, diabetes, pneumonia and the "common cold," believes the *Medical Times*. Conquest of the common cold would alone conserve the population vastly, for it is so very often the initial step of a major infection. A vision of a disarmed pneumonia is by no means preposterous. The time is not far distant when a weekly,

monthly, or even yearly injection of "insulin" will suffice to divest diabetes of all its terrors. Cancer is scheduled for defeat.

A social order in which good hygiene and sanitation, proper diet, decent housing, economic sanity and peaceful relations with neighbors were to prevail would enormously simplify public health (and mental hygiene) programs and further conserve populations biologically and numerically. It is also to be presumed that under civilized conditions of life people would not be panicked by the very idea of parenthood, as is now so often, and so understandably, the case.

PERIPHERAL VASCULAR DISEASE

Simple External Suction

JOSEPH TENOPAR, M D, F A C S and B G P SHAFIROFF, M D, *Brooklyn*

From the Surgical Service, Kings County Hospital

Suction was employed by Bier to produce what he called a "stauungs hyperemie" to increase the natural body forces against inflammation. He also advocated the use of suction chambers as a mechanical aid in restoring motion to immobile joints and paralyzed muscles. He claimed that "a marked hyperemia is produced in the respective joint the consecutive vascularity and serous infiltration of the parts rendering them mobile." Many years before Junod,¹ Bier, and Murray enthusiastically treated many diverse diseases with apneumatic chambers for which they predicted its universal application in medicine.

Landis and Gibbons² in their excellent pioneer studies objected to simple suction on the basis that it caused an increased blood flow and a fall in blood pressure in the terminal vascular system of too short a duration to effect an increase in the peripheral circulation of any therapeutic value. They claimed that suction alone would fill the capillary to venule system up to a point of maximal distention after which time the internal resistance of the capillary bed would either resist the force of suction or would break (rupture of vessel wall) with resultant capillary hemorrhage. They therefore devised a system of alternating suction and pressure exerting its forces on an extremity in definite time cycles, such as a negative pressure of 120 mms Hg for a period of twenty-five seconds followed by a positive pressure of 120 mms Hg for five seconds. This cycle of negative to positive pressure permits the flow of blood from the arterial tree through the arteriolar to capillary to venule system with minimal distension or stasis as well as providing for the return of the blood to the right heart. The sole purpose of the additional positive pressure to the suction is to empty the peripheral vessels. They conclude therefore that "simple intermittent suction with its rest periods would probably be less efficient

since (a) the congestion produced by the cuff would not be overcome and (b) emptying would be slow and incomplete."

It is interesting to note that medical literature offers little reference to the exclusive use of simple suction in circulatory disturbances of the extremities other than the work of Sinkowitz and Gotthieb reported in 1917 for the treatment of thromboangitis obliterans by Bier's method of suction hyperemia, Braeucker's³ use of the same method for Raynaud's disease, and the first rationalization of the modern clinical reported by Reid and Herrmann.⁴

With the increasing conservative trend in the treatment of peripheral vascular disease, we devised a simple suction chamber which permits of suitable negative pressures alone and corrects the main physiological objections mentioned above. Complete and rapid emptying can be accomplished by the simple expedient of applying the suction to the extremity in an elevated position. This emptying occurs whether the system is in an atmospheric or subatmospheric environment. Positive pressure can therefore be eliminated and the advantages of suction afforded, namely a thorough perfusion of the capillary venous bed without stasis and continuous return flow to the right heart. Though this observation was made independently by us without the knowledge of Reid and Herrmann's work, they have originally stated about this subject:

During the early part of our work we employed alternately positive and negative pressures to the extremities, but we soon found that even relatively small amounts of positive pressure frequently caused sufficient compression of the diseased arterial wall to produce extensive secondary thrombosis. It is because of this experience that we feel that an extremity in which the arteries are diseased should never be subjected to any form of therapy which might compress the arterial wall even when that compression only lasts for a few seconds.

Fig 1 Extremity in boot, ready for suction.
Note tube sealing end of boot

We have found that simple elevation of the extremity slightly above the level of the heart is sufficient in most cases to provide rapid and adequate drainage of blood from the extremity. The elevation of the extremity during the treatment with negative pressure is highly important since much of the immediate benefit is derived from the thorough flushing of the capillaries and arterioles as well as the venules and veins of the distal part of the extremity with freshly oxygenated blood and the prevention of venous stasis.

The purpose of this paper is to show that a simple suction device can be used in the treatment of peripheral vascular disease without the necessity of purchasing the expensive apparatus now on the market. The apparatus can easily be assembled in any hospital and can be more generally used by the profession with the knowledge that the same physiological benefits can be obtained as with a commercial pattern. Simply it consists of the regular portable suction machine used for surgical aspiration connected to an airtight chamber or boot by rubber tubing. A small expenditure is involved

Fig 2. Wooden suction chamber

in the construction of the boot. We used three boots, two of which were made of a rust proof tin and one was made of a grade one wood fitted with windows. These can be readily made by a carpenter or tinsmith according to specification. Before the extremity is inserted into the boot, a properly fitting non-constricting rubber tube encircles the leg or thigh. These tubes resemble in appearance the inner tube of an automobile tire and are of various sizes. They are home made but are so constructed that on inflation the proximal circumferential rim is fixed while the outer rim can be expanded distally to fit snugly into the end of the boot (Fig 1-3)

Earlier in the work, regular pressure readings were taken on the manometer connected with the outlet, later this practice was discontinued and the sole guide was the patient's sensation of pain or discomfort for stopping treatment. Rather than interrupted treatments at high negative pressures for short intervals, our treatments are given at minus 30 to minus 50 mm Hg maintained continuously for one-half to two hours, according to the patient's tolerance. It is possible to use suction at a continuous constant negative pressure by inserting small objects between the tube around the leg and the outside to permit a small air leakage. We have had the suction going

Fig 3 Tube which seals end of boot or chamber

The tin boots are of two sizes, one extending above the knee, the other ending two or three inches below the knee. The larger boot is used in cases where involvement of popliteal and femoral vessels are indicated by the oscillometer. The smaller boot is used in cases where pathology exists primarily below the tibial vessels. Generally, it is preferable to apply suction with the entire extremity including the knee in the chamber or boot. The proximal end of the wooden chamber is closed by a rigid rubber diaphragm with a large central hole of a size to enclose the average extremity around the lower thigh. The extremity encircled by its inflated tube seals the proximal end. The outlet on the boot is connected to the suction machine by pressure tubing. The button on the suction base permits the patient to start and stop the negative pressure when the treatment period is ended or the sensation of pain is present

for long time periods at lower than usual negative pressures with good results such as a negative pressure of fifteen-twenty mm for six hours. The treated limb in every case is elevated during the suction period.

Thus far the clinical results are a confirmation of the beneficial effects reported by other workers with the Pavex machine. We do not aim to give a detailed clinical report consisting of oscillometric readings, thermocouple measurements or other physical data because of the small number of cases treated. A limb after treatment was dark red in color and warm to touch, usually much warmer than the untreated side. The patients reported their own perception of this warmth which included the digits especially. Relief from pain was noted in twelve of the sixteen cases treated by this method. Three of these had Buerger's disease, twelve were diabetic arteriosclerotics, and

one was a severe frostbite of the lower extremities. One case developed capillary ecchymosis directly due to suction. Two cases with gangrenous toes considered for amputation healed completely. Six arteriosclerotics reported relief from pain and improvement in walking distance. The frostbite case responded well to suction, improvement in skin texture, relief from persistent coldness of the feet, cessation of walking pain was also experienced. No other treatment was used in any of these cases during the course of suction therapy. From our present data we can conclude that simple suction is a rational method of treatment.

Summary

A simple easily constructed external suction apparatus is offered for further study in the treatment of peripheral vascular disease.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., D.R.P.H., New York City

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Combination of Misfortunes

A man of forty-five who had never read any novels or love stories was in love with his wife and she with him since they married at twenty—one example of a successful union. But just as the *Bourgeois Gentleman* spoke prose all his life without realizing it, so our man discovered his deep affection for his partner and the poetry of his life only after she died. The world was empty without her. "Any noise and I hear her coming." He struggled not to show his weakness, but the tears rushed and blurred his vision. It was not only a moral necessity. He was helpless without her. She had done everything for him and for the rest of the family. He had gone to the shop, but what was that compared with her ability to multiply herself and find a solution to all problems? "I am lost without her, I have lost my wife, my home, and now, my job." Yes, that was the crowning of the tragedy—his job. What a coincidence! It seems strange to him. He had been working steadily ever since "he was a kid" and just now he was not wanted. It would not have mattered, but there were three children and they all needed help. "For myself—who cares? I can be anywhere, I can go any place. And why live altogether?" So he had given up his home, put the furniture in storage—"good stuff, all my penties in there and chosen by her, with her fine taste"—and sent his children to a relation

in another town. The poor always assist one another.

But one day he went to see the children and he learned sad news. His boy of fifteen had almost drowned, he was rescued and it took a long time until he could be revived. He had gone swimming to a place near rocks, where there was a sign "Danger." Asked why he had done that he replied "What should I have done? All the boys go there. I'd have looked like a sissy." Then the father went to the neighbor's and spoke to his youngster and he also said "If I don't go with the other guys, I'll look like a sissy."

That is why this father broke down and is both unable to work and find work. He is sure that under his wife's guidance and leadership none of his children would have put himself in any dangerous situation. His may have been a masochistic nature inclined to hypochondriasis, but the latter may not have appeared if it had not been released by an untoward chain of events.

Encouragement made it possible for him to resume work at his trade, to build up a home again, to bring in his sister as a housekeeper, and to feel more secure about the children's fate.

A woman of thirty-nine is at the peak of unhappiness.

"Look at my hands," she says. There is a coarse and rapid tremor which has been present for several years, ever since her husband was declared tuberculous and had to leave for a City sanitarium where he still is. Then she had to give up the house and go to work as a dressmaker in the same shop which she hated so much and where she had been employed as a girl. The child, now six, is an inmate of an orphan home and can be seen at rare intervals only. Her lungs and thyroid gland are apparently in good shape, her metabolism test registers normal, but her heart is defective. She is tortured by the fear of impending "paralysis" of the hands.

"I am not concerned about myself," she declares, "we don't die twice, but my child will be sent home soon, in another year or so, and my husband will need me too. And my employer doesn't want me in the shop. The old boss didn't look at me and never knew about my shivering hands. But his young son, who just joined the firm, is very careful and the more he watches, the worse my fingers jump. In fact the material shivers away from me. Then he has another

reason. He wants only good-looking and well-bred girls. That should be none of his business."

Indeed she is ugly and worn out and ugliness is pardoned only in those who can cover it with elegant and graceful clothes. She is uneducated, but tries to be polite in her own way. "Every day, excuse me, I take a shower."

"He gave me another month. After that I'll have to quit and wherever I'll go they'll notice my shaking and won't take me. Meanwhile the new boss has cut down the wages, reducing five cents to the dress, from 38 to 33 cents."

She could not finish the month. She cried day and night and felt lonely and lost, ready to commit suicide. Indeed she attempted it once.

She was advised to change her occupation and enter the domestic service, which she reluctantly did. This and the assurance that there was no danger of "paralysis," as well as instructions how to take care of herself, solved the problem, at least temporarily. Her tremor was incurable.

INTERNATIONAL CONGRESS OF RADIOLOGY

Simultaneous projection of pictures and text in three languages will be an unusual feature of a gathering of leading physicians and physicists of the world in Chicago this September, according to Dr. Arthur C. Christie, Washington, D. C., president of the Fifth International Congress of Radiology. Whatever the speaker's language, translation of his paper will be thrown on the screens in English, French, and German so that practically everyone attending the Congress will be able to understand it, he said.

It will be the first International Congress ever held in the United States, Dr. Christie added, and will mark the forty-second year since Dr. William Conrad Roentgen discovered x-rays, and the thirty-ninth year since the Curies discovered radium. The vast progress made in development of the medical and other uses of these two boons to mankind will be portrayed during the Congress, not only through the scientific papers and discussions, but in graphic exhibits.

The Congress will be held at the Palmer House, Chicago, and more than 12,000

square feet of floor space will be devoted to an extensive scientific exhibit to be arranged by scores of hospitals and research laboratories throughout the world. Over 20,000 square feet will be devoted to commercial exhibits, showing the latest equipment manufactured by leaders in the field, ranging from x-ray negatives up to models of million volt therapy apparatus.

A "short-term" medical school will be conducted during the Congress, said Dr. Christie. Eminent leaders in the field of Radiology will conduct short courses. All of the United States radiological societies, including the Radiological Society of North America, American Roentgen Ray Society, American College of Radiology, and American Radium Society, will hold their joint annual conventions during the Congress and will elect officers. At least 500 foreign delegates are expected from 30 different countries, and over 2000 United States physicians will attend. Physicians in other branches of medicine may attend the Congress, according to Dr. B. H. Orndoff, 2561 N. Clark Street, Chicago, general secretary.

EDITORIALS

Thumbs Down on Fraud

The Wheeler-Lea bill now pending in Congress makes a direct and highly practical attack on fraudulent advertising of foods, drugs, cosmetics, and therapeutic devices. By giving the Federal Trade Commission specific jurisdiction over these products, it enlarges the scope of the present Food and Drugs Act in accordance with present day needs.

While the Commission will have no authority to stop the manufacture or sale of objectionable products even if the Wheeler-Lea bill is enacted, control over advertising will go far to banish fraud and misrepresentation from the industries specified. The patent drug manufacturer, the dealer in cheap diathermy and ultraviolet machines, the vendor of psyllium seeds, could get nowhere without highly colored promises and claims which it would take a miracle to fulfil.

In spite of the current cult of sophistication, a paid testimonial, no matter how blatantly false or immaterial, can still gain credence where disinterested expert opinion is refused a hearing. The Wheeler-Lea Act empowers the Federal Trade Commission to stop this sort of advertising where it is dangerous to the consumer.

No one could pretend that this bill

represents the ideal in aggressive governmental action to protect the consumer against fraud. In the absence of a modernized food, drugs, and cosmetic law, with the necessary teeth to make it effective, it is a stopgap of which there is undoubtedly need. Clamp down on fraudulent advertising and you cut down the sale of worthless, overpriced products. This is particularly true of drugs and cosmetics. For this reason the Wheeler-Lea bill deserves consideration in spite of its shortcomings.

A Practical Guide

While physicians who engage in dishonest or flagrantly unethical practices undoubtedly do so with full realization of what their acts portend, a number of practitioners slip from the path of strict professional rectitude for want of authentic information in regard to their duties. This is particularly true in connection with technicalities in the Education and Public Health Laws.

To prevent errors and give the young practitioner a fair start, the State Society has proposed that the Education and Health Departments each issue a pamphlet to new licentiates setting forth what is required of them under the vari-

ous laws and regulations governing medical practice. The Education Department's brochure would explain the procedure for local and annual registration. The Health Department's leaflet would describe the practitioner's duties under the Public Health Law. For licentiates settling in large cities with an extensive municipal Sanitary Code, a statement of local regulations could be included.

It would take a minimum of money and effort to carry out this plan. Compilation of the pamphlets would not be difficult, the cost of printing would be little, the expense of distribution negligible. For the slight outlay entailed, the State would have the assurance that every physician embarking on the practice of medicine understands the legal requirements of his profession, requirements made in every instance for the public good.

The well-intentioned practitioner would also gain by greater familiarity with the statutory technicalities governing medicine. A lapse from strict legality may prove both expensive and embarrassing, subjecting conscientious men to a suspicion of moral obliquity which they do not deserve.

Copper in Diabetes

It has been shown, both by animal experiments and by observations on humans, that copper, when administered orally, has a definite influence upon carbohydrate metabolism.¹ Subjects who have a normal blood sugar content show but slight change in the blood sugar following the ingestion of copper. However, an attempt to produce a hyperglycemia by adrenalin or by a dextrose tolerance test is greatly inhibited by copper.

Schnetz observed that in diabetic patients, the daily administration of ten to twenty mgs of copper sulphate over a period of months produced a marked improvement in the general metabolism. Be-

sides a distinct betterment of the general condition, a reduction in the diabetic hyperglycemia and glycosuria was noted. The insulin requirement was distinctly lowered. In severe diabetics a reduction as high as fifty-five units from the daily dose is reported and in patients with mild diabetes, the copper medication can in some instances completely replace insulin. Any interruption of the copper therapy results in a prompt exacerbation of the diabetic state.

Since copper sulphate in the doses mentioned above is well-tolerated by the body, this form of therapy recommends itself as an additional means of controlling hyperglycemia. In addition to lessening the amount of insulin needed, it is a more pleasant form of medication.

Sulphanilamide Treatment of Gonorrhea

The spectacular results reported in the treatment of gonorrhea in the male by the oral administration of sulphanilamide lead one to believe that finally a satisfactory means for the cure of this disease has been found.¹ Both acute and chronic cases respond equally well. The dosage recommended is forty grains daily until the clinical criteria for cure are attained. These include the disappearance of organisms and microscopic pus from the urine and prostate gland, the absence of all symptoms, and the inability to produce a recurrence.

Reuter noted, in the two glass urine test, a pus-free first glass twenty-four hours after treatment with sulphanilamide was started. Within from five to ten days the urine was entirely clear. In no instance was the infection aggravated by the drug. The side effects of this chemical are weakness, fatigue, sensitiveness of the skin over the legs and occasional tingling sensation in the toes. These are held to be of prognostic value since those who complained of these symptoms early responded best to the treatment.

¹ Schnetz H. *Klinische Wochenschr* 16 664 1937

¹ Reuter F. A. *Med Ann Dist Col* 6 117 1937

The one danger of this form of therapy is that the drug can be purchased over the counter in all drug stores. The large doses required for the cure of gonorrhea necessitate supervision of a physician if untoward effects are to be avoided. Severe toxic reactions have been reported and many will undoubtedly occur if self-medication is encouraged by the wide publicity this drug has had. It should be included among the others which are not allowed to be dispensed except upon the receipt of a doctor's prescription.

CURRENT COMMENT

"A STATISTICAL REFERENCE SHOWS a close relationship between the number of physicians and the number of policemen in the country, there being about 132,000 of each. Apparently the same man power is required to make people behave as to make them get well."—*Printer's Ink*

"THE REPLACEMENT OF NURSE-ANESTHETISTS by M D-anesthetists has been deemed advisable in numerous hospitals. It has also been deemed impracticable.

"We can't simply fire these nurses," staff physicians say. "They've been loyal employees of the hospital for years, and their work has always been satisfactory. Although we'd like to make the changeover, it's impossible."

"Let such men take a tip from one of Philadelphia's leading hospitals. There, a completely simple but nevertheless practical solution has been applied. Instead of discharging its nurse-anesthetists all at once

the hospital is following the policy of merely replacing them by physicians wherever the nurses retire or leave voluntarily.

"This policy creates no friction. No one is thrown out of a job. Yet professional anesthesia is gradually beginning to take its place in the hospital, thereby assuring better service for patients and an opportunity for young physicians to specialize in this branch of medicine."—*Medical Economics*, July 1937

"AS AN OUTCOME OF RESEARCH during the past few years and a knowledge of the biological laws governing human life, we are on the high road to bettering conditions of today and paving the way for a vast improvement in the life of the next generation. Scientific nutrition will play a prominent part in this campaign. A well fed population is a contented population and an essential asset of a nation."—The editors of *Medical Record* of June 16, on the subject of "Nutrition"

"THE AVERAGE DOCTOR is usually too busy attending to his business to spare time, strength or postage to discover what the laity thinks about him and his profession and the way in which it is run.

"But this is a day of lay espionage of the professions, especially of the medical profession. The American Foundation Studies in Government (a group of patriotic and high-minded persons that calls this report "American Medicine or Expert Testimony Out of Court") was undoubtedly motivated by the sincerest and most serious of aspirations when it set out to garner these sheaves of information."—Further editorial reverberations on an excellent piece of work, from the editors of the *Illinois Medical Journal* of recent date.

TO MAKE ILLNESS DELIGHTFUL

To those medical patients who squirm and send their visages through violent contortions every time they take some bitter prescription, modern medicine today offers a pleasanter future.

The explanation, Dr. Bernard Fantus told more than 1000 Western New York physicians at the third annual clinical day of the Alumni association of the University of Buffalo School of Medicine in Hotel Statler, lies in "disguised medicines."

Thus prescriptions of the future—and a beginning in them is being made now—will have, not sour or bitter or nauseating

tastes, but the tastes of licorice, raspberry, cherry and some new, pleasantly sweet preparations.

In this way, modern medicine hopes, not only to ease the taking of prescriptions, but to induce the public not to waste its money on proprietary preparations of unknown content, many of which are more expensive, too, than legitimate medical concoctions.

"Ancient medicine was nasty medicine; the medicine of the future will be pleasant," emphasized Dr. Fantus, who is professor of therapeutics in the University of Illinois School of Medicine.

To the Editor

I should like to congratulate our State society as well as the society of Westchester County on the stand of free choice of physician for indigent patients at an ethical fee paid by the government. I believe the A.M.A. has taken the same position

Now that we have had our say, I can almost hear the politician say, sneeringly, "So what?" What are we going to do about it? To force the politician to act for the welfare of the public, we have to convince the public that it must act in its own behalf, and the only way to awaken the public is by means of publicity—show the people, particularly the indigent, the importance of a patient in being able to secure his own physician at an ethical fee. They still vote. Make public officials, especially the mayors, commit themselves on their stand. In local elections, the support of citizen organizations, non-partisan and partisan, is important in putting our ideal across—articles in the newspapers and speeches by prominent citizens before civic organizations will help considerably. To present it to the nation as a whole, publicity on the radio, (speeches and sketches) and in popular magazines, is essential. Here we could get the financial support of such ethical firms as Hoffman-La Roche, Parke, Davis & Co and others, who realize that the welfare of the independent physician is associated with their own. Local medical societies and the huge financial resources of the A.M.A. can be utilized for this vital purpose. Winning this fight will save the life of the medical profession as we have known it, and losing it will result in an opening wedge for state medicine, where the physician will be enslaved to the will of the mercenary politician. We must act now to stem this vicious movement.

Now, what can we do about cleaning our own house? Should we permit physicians who insist on working at a cut-throat salary on a contract to the city, to remain undisciplined even after due warning from their society? The medical society has a "big stick," and like Theodore Roosevelt, it should speak softly, but use the big stick

where necessary. If such physicians find that they are excluded from the recognized hospitals and medical societies, they would change their unethical behavior

Yours very truly

Julv 2, 1937

E H ALLAR, M D

Virgin Islands Seek Physician

32 Pearl Street
New York City

Medical Society of State of New York,
2 East 103 Street,
New York, N Y

Gentlemen

We have received a letter from our correspondents in St. Thomas, Virgin Islands of the U S A, Messrs The West Indian Company, Ltd, in which they inform us that there, in all probability, would be an excellent chance for a young doctor to work up a profitable practice on St. Thomas

It has occurred to us that this might be of interest to some young doctor, and that it might be feasible for you to bring this chance to the attention of the medical profession through one of your regular publications. We know that The West Indian Company, Ltd, will be glad to furnish all possible information in regard to conditions on St. Thomas to anyone who might apply for such information

We shall be glad to hear from you whether you think that the above plan is possible

Yours very truly,
GUDNA AMERICA LINE INC,
Per RASMUS HANSEN

July 6, 1937

Pan American Medical Association

745 Fifth Ave
New York City

To the Editor

The Executive Committee of the Board of Trustees takes great pleasure in announcing that the "Queen of Bermuda" has been chartered for the Seventh Cruise-Congress. As you know, we had this boat for the last Cruise and it proved to be most ideal for our purposes. Following is the itinerary

Leave New York	January 15, 1938
Arrive Havana	January 18
(4½ days and 5 nights in Havana)	
Leave Havana	January 23
Arrive Port au Prince	January 24
Leave Port au Prince	January 24
Arrive Trujillo City (Santo Domingo)	January 26
Leave Trujillo City (Santo Domingo)	January 26
Arrive San Juan (Puerto Rico)	January 27
Leave San Juan (Puerto Rico)	January 27
Arrive New York	January 31

The main part of the Congress will be held in Havana. There will be three days of scientific sessions with operative clinics. These will be divided into sections for the various specialties. This year we have four new sections: Tuberculosis, gastroenterology, dentistry, and industrial medicine. Meetings will be arranged with our medical colleagues at the other ports of call.

The Hotel Savoy-Plaza in New York and the National Hotel in Havana will be our official hotels.

Travelways, Inc., have chartered the "Queen of Bermuda" on behalf of our Association and will act as our official Travel Agents. As this Congress promises to be the most successful ever held by the Association, it would be highly advisable to book reservations as early as possible with Travelways, Inc., who will make every effort to satisfy the requirements of the members of the Congress. Applications for reservations should be addressed to the Pan American Medical Association at 745 Fifth Avenue, New York City.

The program committee would be pleased to receive applications for the presentation of scientific contributions.

Cordially yours,

JOSEPH JORDAN ELLER, M.D.
Director General

July 3, 1937

THE RABIES MENACE

The alarming situation which prevailed throughout the country last year in relation to dog-bites and rabies appears even more menacing this summer. During the recent warm days, according to newspaper reports, more than a hundred persons have been bitten by dogs daily in the city of Chicago alone. This represents more than a fifty per cent increase over the number of bites during the similar period of 1936. More heads of suspected animals have been examined, and the number found positive for rabies has also increased more than fifty per cent.

Although conditions in Chicago may be more serious than those elsewhere, the situation is also actually or potentially critical in all other districts where dogs, especially strays, are numerous, observes the *Journal of the A M A*. As judged from reports from all over the world, rabies is generally far from quiescent.

The extent to which informed sources recognize the great danger of rabies is illustrated by the fact that the Rockefeller Foundation began a program of laboratory and field work on rabies in 1936. This disease, according to the foundation report, has become increasingly menacing, particularly in some of the Southern states. With

this recognition that some regions are more threatened than others, it must also be emphasized that no areas where possible carriers of rabies are present can be considered exempt. The Rockefeller report also states that there has been little research on this disease since Pasteur's time. A quicker and more positive test for rabies in animals and a less cumbersome method of vaccination are badly needed.

All these facts point to the conclusion that immediate and coordinated action is necessary. Rabies is a disease in which individual efforts are relatively helpless unless aided by the full machinery of social organization. The press, public health officials, the police and physicians—in both their individual and their official capacities—should take steps to combat this threatening situation at once if a considerable number of unnecessary deaths is to be avoided. In the face of the now existing information as to the frequency and rapid spread of rabies among animals, it seems criminal to postpone action until the disease is identified in human beings. Because rabies is primarily a disease of dogs, it seems likely that this campaign will have the whole-hearted support of all the animal humane societies.

Presidential Address

The Partnership Idea in Public Health

CHARLES H. GOODRICH, M.D., Brooklyn
President, Medical Society of the State of New York

In the Army we were taught by old timers to shift responsibility to some one else. (They tell us that this is fashionable in all Government Departments—except Health Departments) This teaching to “pass” what they call “the Buck”—“went against” what they call “the grain.” We had long practiced the habit of grasping red hot responsibilities with our bare hands or frank brains and receiving painful burns of both regions. Others then carried forward the idea with the help of asbestos gloves and well-insulated brains and at least we had the satisfaction of seeing fruition established and had been content. However the army way is easier and more peaceful and we have been educated.

The day has come however when we have a heated responsibility thrust into our hands, and we must grasp it without gloves or insulation. We are confident that we shall not even be scorched for we are among friends whose objectives are like ours.

First We are here to propose and analyze the slogan “Every physician a Deputy Health Officer,” and to discuss with you how to bring it about.

In a recent address at Rochester we said “The license to practice medicine implies greater obligation to the public than diagnosis of disease and treating patients for a consideration. What implications challenge our special interest during the coming year?”

One of these “Although already initiated by your officers and committees, active individual cooperation with Health Departments and Health Officers seems indicated. In some large counties the Public Health Committees accomplish wonders. More wonders can be done by general membership insistence that all are live participants in the health projects of the community. The public expects this. Commissioners hope for it. Law implies our interest and cooperation. We are fit. There is much to be done. Every member can do his share in his own community. Every county society is urged to adequately enthuse its membership. The slogan “Every physician a Deputy Health Officer.”

That this is not actually and fully so is due to a multitude of causes. Mainly it appears to be because, aside from their essential monitor services (vital records), the central thought of Health Departments has been prevention while the practitioner's mind is concentrated upon diagnosis and treatment of disease. This despite universal individual interest in both. Recently in this State two cooperative efforts in “disease control” have been undertaken in pneumonia and syphilis. In these efforts many physicians have been engaged, those officially charged with duties by the State Society and those whose services have been required to complete the program. The results thus far in pneumonia control are impressive and will grow in importance with continued cooperation. Concerning this the State Medical Society has registered universal enthusiasm. Thus it is easy to integrate in health service the officials of the State Medical Society and those practitioners who have an interest in part-time employment in a specific project. Our future problem is how to engage the interest of all physicians in health work regardless of or in consideration of some form or degree of compensation. Here we meet with difficulties concerning which we must be brutally frank. If these are not disposed of in some way we shall fail.

1 The taxpayers of a community or state determine how much it will pay for health service. This provision varies widely so our results are variable. “Scrimping” of these funds as compared with other social appropriations is often charged. Adequate appropriations for complete service are lacking in the majority. Perhaps New York City is the outstanding example of lack of financial appropriations for its extraordinary health needs, if we except the appropriations for new Health Center Buildings. What is needed is greater appropriations for personal services. (We interpolate that present results indicate remarkable efficiency in its Health Department. Moreover we should not forget the eighty-six voluntary health agencies who contribute to this result.) Thus the representatives of the taxpayers must be afforded new and modern intelligence regarding the needs.

2 Citizenry, or its rank and file, regard

*Address delivered at the Annual Conference of Health Officers and Public Health Nurses,
Saratoga Springs, June 22, 1937*

specific disease prevention as a "negative accomplishment." This is not dramatized in the public consciousness" (Parran). Physicians in personal contacts as well as Departments in public contacts, should stage these dramas early and often.

3 The general practitioner of medicine has been so forgetful of his own pecuniary gain for centuries that unfair advantage of his consideration of others has been taken by institutions, government agencies, and the public in general until now the rank and file with increased costs, their "backs to the wall" are compelled to ask of any invitation to participate in anything "What do I get?" In this connection we quote the classical declaration of Dr Frederic E. Elliott, "Every community has a vital stake and resource in the prosperity of its physicians." They must be thinking of their great work unworried by financial embarrassment.

Thus while keeping these three difficulties in mind we raise the question "How can every physician become a deputy health officer?"

Henry Vaughn thought this could best be accomplished by closing clinics and sending preventive specific prophylactic measures to the physicians' offices, and that when all results were totalled and balanced greater prevention could be accomplished at reduced cost to taxpayers—and he proved his claim regarding diphtheria. That this could be done in any community with Vaughn's ability, administrative and pecuniary backing and the professional talent available, would seem a reasonable proposal. However, with most competent department heads, with free hands, and possessing peerless professional personnel, the City of Yonkers in Westchester County has just given up an anti-diphtheria campaign using physicians' offices, as a failure, and clinics are to be reopened. Also in Northern Westchester County the plan has given inadequate results. Now back to Detroit. Perhaps the most adroit condition in the Vaughn plan was the agreement arranged with the Wayne County Medical Society that the participants in this plan should attend lectures by health officers twice monthly and learn something of the technic as well as the spirit of Health Officers. This was not a feature in Westchester County. We hold that that technic and that spirit are essential to majority participation and success.

The outstanding cause of criticism of the Vaughn plan has been the extra expense with which it is charged. The recorded results of the first cooperative effort (diphtheria) clearly demonstrated the total economy to the City, although actual compensation to workers was greater than under the clinic plan.

In a recent presentation of Detroit work in "Intensive Case finding in Tuberculosis," delivered at the Atlantic City meeting of the American Medical Association, Vaughn states "Health Departments have been prone to accept crumbs from the monies spent for social betterment." He proceeded to demonstrate the wisdom of spending a considerable sum for the purpose of saving a much greater amount. He cited as an example of wasteful expenditure in one city an annual appropriation of two and one half million dollars to hospitalize tuberculosis cases. Twenty-five hundred beds are provided, equal to more than twice the annual number of deaths. He contends that with intensive early case finding (which costs somewhat more than the usual discovery of cases in later stages of disease) many lives and great sums of money could be saved for communities. In the instance he cites he suggests that "much if not all of the money being spent for hospitalization should never be spent. There should be no cause for its expenditure. Finding the early case will reduce hospital load and expense and save money. The diversion of a fraction of this saving in hospital bills to adequate case finding facilities would be good economy." He details the added personnel required in Detroit, including forty-five new public health nurses ("the total number of Health Department nurses on June 1, 1937 is 430"). His program is more comprehensive than the earlier undertaking.

As is generally recognized the practicing physicians of this state consider the Detroit plan of health work the best thus far advanced. Our impression is that its principles have yet to be accepted *in toto* by many of the practically experienced health workers. We devoutly believe in evolution—not revolution—in matters of great importance. (This also is an outstanding feature of the Detroit efforts in specific prevention.)

Particularly in view of the latest developments, our first practical suggestion for attempting further integration of the general practitioner of the State in health work is that the Health Department of the State and the State Medical Society make a joint study of the Vaughn Plan at the arena in Detroit.

Our second suggestion is that the next recommendation come for the other arm of Medical Service, the Health Department. Designating "arms" of the service calls to mind the time (in 1920) when the late James M. Barrie was crippled by neuritis in his right arm which was practically paralyzed. He always penned his plays laboriously in fine script never using type-

writer or dictation. Soon after this shocking disability came he astonished his friends by quickly training himself to write with his left hand. Late in the same year he wrote "Mary Rose" his favorite play. When some one observed that "Mary Rose" was different from his other plays Barrie said "It is surprising what different ideas come down one's left arm than down the right one."

So the Department and the practitioners are the two arms of the service. It makes no difference which is right and which is left for both have speech centers. Through us both public health enterprises can be ambidextrous.

The second item in our presentation concerns our conception of Preventive Medicine in general in addition to specific preventive measures. From the aforementioned address to the House of Delegates, which was unanimously approved by that body we again quote

Our profession is vocal concerning preventive medicine. Practically we have produced a certain few specific immunizing measures and have conducted campaigns to popularize them or to provide for required adoption by community or state. This is specific preventive medicine. Otherwise preventive medicine is a field so vast and so promising as to fascinate dreamer and worker. Ample reservoirs of information are reposing in our great libraries. What percentage of these are practically utilized? In what degree is the profession informed? How much have we taught our public?

When we say preventive medicine we mean all sorts of measures and provisions for preserving life and health. We include sanitation, hygiene, exercise, diet and drinkables, housing, ventilation, lighting, heating and in general, the conduct of homes, schools, and institutions. We think of industrial diseases and injuries, street injuries, fire injuries, and accidents in sports. Also upper respiratory infections, epidemic and endemic, precancerous irritations, focal infections of teeth and tonsils and their relations to arthritis, and various infections of the respiratory and gastrointestinal tract. The degenerative diseases are increasing their toll of devoted tense workers especially among our own kind. Prevention of asphyxial deaths (including anesthesia) is an important item. Companion with this are the varying degrees of anoxemia suffered by many unconsciously and unnecessarily. We think of maternal welfare and the care of the healthy child. (In this we have made an appreciable start.) Diseases of animals must be considered especially as transmissible to man. All of the infectious diseases can be

reduced to a minimum, notably tuberculosis and syphilis. There is the physical welfare of the blind and deaf. We think of the mentally deficient child and the too precocious child. Personal hygiene and mental hygiene are significant factors in complex living. Electricity including the x-ray menaces human safety. Also important is the hygiene of ports and ships that arrive and depart. Atmospheric pollution by smoke, dust, sand, carbon monoxide, and gasses innumerable should be controlled. Moreover there are those numberless instances of acute infections and minor or major injuries in which prompt treatment in the hours of inception or reception may be realistic preventive medicine. Such treatment may prevent serious or critical illness, loss of time, earning power, and perhaps function, for the patient. As a corollary the physician would have many easy tasks instead of a few huge heartbreakers.

Preventive as well as curative medicine can be advanced by an increased percentage of recorded postmortem examinations. This may call for elaborate endeavor along special lines.

This is sketched all too incompletely the field of preventive medicine. Much of it can be cultivated for the individual by the masterly complete periodic health examination. This is an accepted procedure in theory but with a low percentage in practice. If universally sought and practiced it would require the patient devotion of much time and great skill. In that day we must be ready with schedules, record blanks and equipment—material and mental, to do thorough work. When largely demanded by the people many specialists in this line will be needed. Therefore

We recommend that during the coming year in county and district branch meetings the subject of preventive medicine be actively presented, discussed, and that its practice by the profession be encouraged in every possible way, and

We recommend that contributions on preventive medicine to the STATE JOURNAL be offered by the membership and sought by the Journal Management Committee, and

We recommend that whenever and wherever possible lay audiences throughout the state be provided with addresses or lectures on preventive medicine, such provisions to be made by county societies, District Branch officers, by the Public Relations Bureau of the Society, or by concerted action.

In connection with this last recommendation, may we remind you that preventive medicine can arrive at its goal only when an eager enlightened public apply for it.

They must be convinced of the advantages obtainable

No idealistic enterprise is free from difficulty. As to preventive medicine, in its broadest sense, the public has little interest, little appreciation of resources at our command, and no enthusiasm for demanding such service. The attempts to establish periodic health examinations as a preventive measure produced feeble public response. There is a persistent disregard of well-known health laws by even the most intelligent persons, often revealed by the physician or observed in current reading. The indifference of the majority of medical practitioners exists because of lack of public demand for the practice of preventive medicine. This we hope to overcome by our own effort through spoken and written word.

There is usually a definite delay in applying the practical knowledge acquired concerning scientific development, what the great Parran has called "a cultural lag." For instance we were scientifically equipped for syphilis more than twenty years ago—and we are only now just beginning the great work.

So we have for some years been scientifically equipped for a masterly program of prevention of injury and disease. Many isolated efforts have been admirable but they need cohesion and general participation to organize results. Moreover real far-sightedness and accuracy of perception are needed.

Through their physicians and nurses, health departments are equipped to spread truths concerning preventive medicine and particularly to emphasize the importance of complete periodic health examinations. The bulk of the detail work must devolve upon

the practicing physicians and we must be more completely prepared for it than heretofore. We believe that hearty cooperation is necessary, entirely possible, and will be cordially welcomed by our membership.

We believe that in this work it is particularly desirable and important to establish invariably cordial cooperative relations in each community. We shall make constant efforts to do this on our part, through the County Medical Societies and District Branches as well as in the administrative organizations. The community cooperation must be vivid personal work, yet personal interests must be forgotten if the public is to be capably served with a complete program.

Consider how unselfishly men of limited spirit and devotion have heretofore labored to establish preventive medicine in its logical position in the realm of medical service. Their discoveries and accomplishments are on record. A broad knowledge concerning needs and methods are at our disposal. Remedial care is only a fractional application of what we know. Preventive medicine is the competent response to many questions which persons, organizations, and governments are asking of us today.

Thus it is that we desire to help you in the details of your health work so that it can be expanded and perfected. We seek your help in popularizing the idea that preventive medicine and surgery can prevent much of disabling and death-dealing pathology. Together we can join hands in forming a protective circle about our citizens—to guard them against threatening circumstances. This will contribute to the solidarity and efficiency of their families and therefore to the welfare of the Empire State.

SUMMER HEALTH BROADCASTS

Station WQXR has arranged a series of summer health talks, to be broadcast each Monday from 3:45 to 4 P.M. under the joint auspices of the Medical Information Bureau of the New York Academy of Medicine and the New York Tuberculosis and Health Association. The first in the series, delivered by Mrs. Edith Collier of the United Parents Association of New York City, was on "Camping from the Viewpoint of the Parent," given on June 7. Other speakers scheduled are Dr. Jesse A. Tolmach, Assistant Attending Dermatologist at the Post-Graduate Hospital of Columbia University, Dr. Eugene F. Traub, Chief of the Skin Clinic,

Skin and Cancer Unit, New York Post-Graduate Hospital, Dr. Louis F. Bishop, Jr., Associate Visiting Physician at Bellevue Hospital, Captain Charles B. Scully, Director of the Life Saving Service, New York Chapter, American Red Cross, and Miss Ethel McGary, Assistant Director, Life Saving Service. In Charge of Women's Programs, New York Chapter, American Red Cross, and former Olympic Champion. The topics include "Good and Bad Effects of Sunshine," "Summer Skin Infections and Irritations," "Why Accidents?," "Learning to Swim" and "Swimming as a Sport for Women."

Public Health News

School Medical Leadership and Education of the Public

RICHARD W. WEISER, M.D., *Kenmore*
President, N. Y. State Assn. of School Physicians

At this time when State Medicine is occupying the limelight in the practice of medicine of the future, we physicians are waking up to the fact that education of the public to its evils is the only solution to the problem. The opportunities for that education have been with us in abundance at all times but we have failed to take advantage of them until the roar of the flood waters is almost at our back doors. We have been warned to set our affairs in correct order at home before attempting to straighten out the muddle that confronts others, but have we?

This article is only going to touch upon one phase of medical leadership and that is medical administration and supervision in the Public Schools of the United States. Medical leadership in colleges and universities has been on a much higher plane than that in the public schools because the leadership has been on a full time basis instead of a part time basis as is the case in most of the Public Schools.

I am not placing an indictment against all part time school physicians because in many small communities part time service is entirely sufficient, and full time service would be economically unsound. But part time service in most of these communities does not perform the service it should. Yearly examination of pupils at twenty-five or fifty cents a head makes up all the medical leadership the school physician has on his school. When his examinations are ended what few ideals of health education and leadership in the school that he was able to get across at the time of his examinations leaves with him. Teachers, principals, supervisors, and superintendents are dependent upon textbook authorities for their health education principles.

Theoretically most of these principles are sound but nine times out of ten they do not take care of the immediate health problems of that community. The physician of that community who is cognizant of the changing health conditions and who could be a factor in working out a health education program that would utilize local health problems and communicable disease out-

breaks for education of the public and pupils in the school is rarely consulted because his contact with the school only lasted while he was examining the school children at the beginning of the year.

The solution to this problem is to hire the physician on a school year basis at an adequate salary so that he can spend at least two hours daily at his school throughout the year. The additional time after physical examination of the pupils would be devoted to examination of pupils returning after a communicable disease, supervision and instruction of teachers in daily room inspections, recommendation to principle for exclusion from school of pupils with communicable skin eruptions or suspicious symptoms of a communicable disease, recommendation for gym excuses or curtailed physical activities, inspections of the sanitation of the plant, lectures and talks to the pupils on pertinent and timely health subjects, supervision and direction of health education projects, lectures to teachers on communicable disease prevention and first aid, examination of teachers and employees before starting duties, and a host of other items that would arise from time to time. All of this work would be entirely limited to education and preventive medicine. Diagnosis and treatment would not be permitted. Provisions for vaccination and diphtheria inoculations would be the responsibility of the parent and the family physician. Under this type of part time school medical leadership the pupils and parents would both be educated in the latest and best health procedures. My superintendent of schools has always adhered to the principle that if the pupil is properly educated, the pupil in turn will educate his parent to everything that is new and worth while. My experience of four years of full time school medical leadership has taught me the same principle.

Now let us consider the larger school districts where the school population is over 3000. Employment of part time physicians on the basis that I have just finished illustrating in sufficient numbers to take care of the pupils to not more than

1000 pupils per part time physician would be practicable. But for greater service and efficiency a full time physician for each 3000 students who would not be allowed to do any private practice on the side would be of greater value to the community and physicians. Whenever there is a part time position open in a community most of the physicians apply for the position with result that often political favoritism appears and ill-feeling abounds among the physicians for a position that only one with the best qualifications should have.

Some of the qualifications that should be required in a school physician are ability for administration and supervision, tact and a pleasant personality, ability to handle children, special knowledge of pediatrics or orthopedics, or eye, ear, and throat, ability and desire to teach and lecture, and plenty of common sense. The right type of school medical leadership can only be gained by medical men who make a specialty of school medical administration and supervision. With their opportunities for educating the public they can be a valuable force in correcting the many abuses present where part time service is unsatisfactory. They can give their full time to a service of educating the pupils and parents in the latest and time proved health facts as well as showing them the importance the family physician can play through early diagnosis and treatment and the use of accepted immunization procedures.

Full time medical leadership in the Public Schools of this nation is only in its infancy. The State of New York with one of the finest educational systems in the United States has less than 100 full time medical men in the Public School system. We need qualified physicians who are willing to prepare themselves for this field of work. There are many lay individuals in the Public Schools of the nation who have the title of Supervisor of Health Education. If we as physicians do not take over the leadership and direction of school health programs then we can expect the lay individual who spends a postgraduate year in Health Education subjects to direct the school health program. Are we going to allow lay leadership of school health programs or are we going to recognize that there is a young specialty in our midst that needs the support and encouragement of all the physicians of the nation? That specialty is "Fulltime School Medical Supervision and Administration specializing only in Preventive and Educational Med-

icine and absolutely hands off Diagnosis and Treatment."

Too many physicians fear that any full time medical position is just one step closer to state medicine. They are still asleep to the fact that we in full time public health service have the opportunities and time to educate the public in the right type of medical practice and health education principles whereas the busy practitioner of medicine or the specialist does not have the time nor opportunities afforded us. If we are given the wholehearted support of the entire medical profession and medical men are placed in full time positions where they can educate the public then the fear of state medicine would not be hammering at our doors.

Do all you can *now* to promote full time public school medical leadership wherever the school enrollment is over 3000.

As President of the New York State Association of School Physicians, I know I voice the opinions of our members on the subject of school medical leadership. We must not allow ourselves to be crowded out of this leadership by lay health educators. We need thousands of physicians throughout the nation to take up this important work on a full time basis. Nonmedical groups are specializing in optometry, chiropody, and other branches, all because we did not recognize the need for more members of our own profession specializing in these fields of work for which the public was clamoring.

If after reading this article and you would be interested and feel that you have some or all of the qualifications that are necessary to make a good medical supervisor then write to the Departments of Education in your own state and find out what special qualifications they require for you to take a school position as a licensed physician. If they have no special qualifications except the ones you already have then write to your nearest university and find out what courses they have that would help you to become a good school medical supervisor. A good course in Health Education Methods is usually a basic requirement and an excellent course to start with. Extension courses in Public Health are very helpful to prepare a physician for school medical leadership. Leading universities usually have a large variety of these courses that run from four to six weeks during the summer.

In closing let me point out to you again that full time public school medical leadership is strongly needed throughout the United States. With its foundations laid on preventive and educational medicine it

will never invade the field of state medicine which provides for diagnosis and treatment.

Full time public school medical leadership can be one of the strongest factors in helping to educate the public to the importance of early diagnosis, treat-

ment and immunizations by the family physician and specialist, as well as to educate them to the fact that these are all personal services for which they alone are responsible and not the school or state. Lend us your support now by adding more of your members to our ranks

Prognostic Significance of the Tuberculin Reaction

The diagnostic value of the Von Pirquet cutaneous reaction has long been unquestioned. More recently much interest has been aroused in its possible prognostic significance through studies of variations in individual sensitiveness shown by delicate methods of testing. Dr Watson's conclusion is that pronounced sensitiveness to tuberculin is an advantage to its possessor whether he has latent or clinically evident disease. This is because of a satisfactory supply of an activating substance in the blood serum which he calls "ergine," which breaks down circulating tuberculin into an irritant body producing toxic phenomena and some other unknown substance or substances.

Ninety-six cases of clinical tuberculosis were studied from 1925 to 1933. Reactions to the tuberculin test were minutely observed and the cases were classified as (1) those where a strongly positive reaction was obtained, (2) those where a strongly positive reaction was not obtained. Observation of these cases six months later showed that fifty-five per cent of those who had not reacted strongly were prognostically bad, while only seventeen per cent of those who had reacted strongly were in a like condition. Of the former eighteen per cent had died, of the latter only four per cent.

In 1933 the survival rate for the whole group was fifty-three per cent, of the strongly positive group fifty-six per cent, of those not strongly positive forty-two per cent, or a spread of fourteen per cent in favor of the strongly positive group. Selecting only sputum positive cases from the whole group results were similar but with a lower differential, eight per cent.

Further evidence of the prognostic significance of the strongly positive reaction may be deduced from the fact that such pronounced reactions are usual in cases of extra-pulmonary surgical tuberculosis and that there is little tendency for these localized lesions to become generalized.

Again there may be cited the accepted vulnerability to tuberculosis found in the "virgin soil" of primitive races as illustrated by the severity of the disease among American Indians or in Professor Cummins' studies among the natives of South Africa. Dr Cummins speaks of the "natural liability" to tuberculosis infection associated with "virgin soil" as a "dangerous defile at the very start of the road toward immunity."

It is a familiar experience to find a reduc-

tion in strength of the tuberculin test or its disappearance during the acute stage of a concurrent infectious disease. This fading away of the reaction may be evident in measles, typhoid, influenza, acute rheumatism, pneumonia, smallpox vaccination, chickenpox and whooping cough. Realizing the frequency with which some of these appear to stimulate tuberculous activity it is reasonable to suppose that the disappearance of the skin reaction represents an embarrassment of the organism in its struggle against an existing tuberculous infection.

Professor Heimbeck's experience and similar observations of Spehl and Thys in Brussels in the study of tuberculosis morbidity among nurses are introduced as further indication of a certain prognostic significance to be drawn from variations in intensity of skin reactions in adults.

The Author's Hypothesis of the Significance and Meaning of the Tuberculo-Cutaneous Reactions

Before drawing final conclusions from these and other observations the question of the mechanism of the tuberculin reaction itself confronts us. The following experiment of Calmette is illuminating. When tuberculin is introduced into the conjunctival sac of a non-tuberculous subject no reaction takes place. If blood serum from an actively tuberculous patient is introduced similarly in another non-tuberculous subject there is still no reaction. If however tuberculin be mixed *in vitro* with blood serum from a tuberculous patient and the tube kept for a given time at a given temperature and then injected into the conjunctival sac of a known non-tuberculous subject, a prompt reaction takes place.

From this it may be concluded that Tuberculin *per se* does not cause this reaction and serum from a tuberculosis patient does not cause it. There must, therefore, be

a substance in the serum of the tuberculous patient which acts on the tuberculin to liberate something causing the toxic and irritant phenomena in the eye

Living tubercle bacilli flourishing in a patient's body produce a substance resembling tuberculin. This comes in contact with the blood serum of the infected individual and the test tube experiment above described is repeated. The organism, as in other bacillary invasions, should now give a protective response. A substance appears in the serum which so acts on the tuberculin as to disintegrate it into (a) an irritant body producing toxic phenomena, and (b) some other unknown substance or substances. The author suggests the name "ergine" for this substance and assumes that the action of "ergine" on tuberculin is a stage in the elimination of tuberculin from the infected organism. Since constitutional and focal reactions terminate favorably in a large number of tuberculous cases, it is also reasonable to assume that the toxic body (a) is combated by the elaboration of some anti-toxic factor which disposes of and eliminates the products of the action of the "ergine" on the tuberculin. Furthermore, it is again reasonable to assume that the more sensitive the organism is to tuberculin, i.e. the smaller the concentration of tuberculin required to give a response of "ergine," the more quickly will the tuberculin, collected or elaborated in that body, be disintegrated and disposed of.

Calmette found that if a guinea-pig inoculated with living tubercle bacilli, was given gradually increasing doses of tuberculin (1) it became increasingly difficult to produce the reaction phenomena in the animals under treatment with tuberculin. However, such pigs always reacted to massive doses (2). The serum of these treated animals contained nothing capable of neutralizing tuberculin *in vitro*, nor of passively immunizing other guinea-pigs against tuberculin (3). The power of absorbing large doses of tuberculin without reaction was soon lost by the animals if the injections were suspended (4). The lesions

of these animals did not tend to progress more slowly than the lesions of the infected but untreated animals, but tended to progress more rapidly than in the controls.

Conclusion

There does not seem to be, at least in the guinea-pig, any relation between the power to absorb tuberculin without reaction and the power to successfully combat tuberculin infection, i.e., tuberculin per se is harmful even before the "ergine" has acted on it to produce toxic phenomena and further in the guinea pig at least even more harmful than the "erginised" tuberculin.

The process of elimination of tuberculin consists of (a) a response of "ergine" immediately followed by more or less reaction phenomena, (b) elimination at a varying rate of the results of the action of the "ergine." Organisms with quick and efficient "ergine" response dispose of their tuberculin piecemeal, obviating toxin saturation. Organisms with a slow or late "ergine" response permit the accumulation of tuberculin before "ergine" appears and functions with the resulting production of sudden large volumes of toxin.

One is now in a position to state the following hypothesis. Since toxin saturation of tissues is undesirable, since accumulation of tuberculin in the tissues is undesirable, and since the evolution and action of an "ergine" is an essential factor in the prevention of both, then acute sensitiveness to the presence of tuberculin in the tissues leading to "ergine" formation and action before large amounts of tuberculin have accumulated tends to facilitate the elimination of the latter and prevent toxin saturation of the tissues, i.e., *sensitiveness to tuberculin is of advantage to the infected organism.*

The power to give a strongly positive Von Pirquet reaction is direct evidence of such sensitiveness.

Prognostic Significance of the Von Pirquet Cutaneous Reaction in Adults. Wm. G. Watson, M.D. *Ch. B. Tubercle* March 1937.

A TIMELY WARNING

High pressure salesmen of x-ray and radiograph outfits have flooded the country with equipment which is sold for reasons of greed rather than health. Dr. Frederic E. Elhott of Brooklyn told the section on radiology at the State Medical Society convention in Rochester. He said

"Literally thousands of fluoroscopes and bedside units have been installed and the overcredulous doctors have undertaken to reap the harvest. But the poor doctor is left to a sorrowful realization that the purchase of an x-ray generating apparatus is the smallest item in the equipment."

Medical News

Chautauqua County

DR. GEORGE EDWARD SMITH, of Dunkirk, who died on June 18, was a former president of the Chautauqua County Medical Society. He had practiced in the county 51 years.

Columbia County

THE WOMAN'S AUXILIARY to the Columbia County Medical Society held a picnic on lower Rhoda Lake on June 18. The Auxiliary also held a luncheon meeting on June 3 at the Columbia Country Club. Mrs. F. L. Sullivan, of Scotia, gave an interesting resume of the state auxiliary meeting at Rochester. She reported a total of 900 members in the state, and thirteen counties organized. Only six per cent of the doctors' wives are members, "which shows that we still have large fields to invade." The next regular meeting of the Auxiliary is slated for October.

Cortland County

DR. ANTON W. SOHRWEIDE, dermatologist, of Syracuse and Ithaca and associated with the medical school of Syracuse University, was the main speaker at a meeting of the Cortland County Medical Society on June 18 at the library auditorium. The topic was "Common Skin Diseases of Interest to the General Practitioner."

Dutchess County

DR. LONDON H. THATCHER captured low net honors from a large field in the County Medical Society tournament at the Millbrook Golf and Tennis Club on June 9. Turning in rounds of 46 and 47 for a gross of 93, Thatcher was aided by a 27 handicap for a 66. Dr. Gordon MacKenzie had a 69 net for second with 36-37-73-4-69, while Dr. Maxwell Gosse was third with 79 having 48-51-99-29-70 and Dr. Joseph Cumming next with a 71 net, having 48-53-101-30-71. Dr. John R. Ross finished fifth with a 76. Dr. Gordon MacKenzie captured low gross with his 73. Dr. W. Hayes had second low gross with an 81, Dr. J. H. Morris had 41-44-85, Dr. Gilbert MacKenzie 43-43-86 and Dr. John F. Rogers 46-42-88.

Franklin County

THE SEMI-ANNUAL MEETING OF THE

Franklin County Medical Society was held at Saranac Lake on June 9.

The morning session consisted of a surgical clinic at Saranac General Hospital conducted by members from Saranac Lake. After lunch the business meeting was held in the John Black Memorial Room with the president, Dr. Daisy H. Van Dyke, presiding. The nominating committee presented the following report on officers for 1938:

President—Dr. Daniel M. Brumfiel

Vice-President—Dr. E. M. Austin

Secretary and treasurer—Dr. D. H. Van Dyke

Censor for 3 years—Dr. J. N. Hayes

Delegate to State Convention—Dr. C. E. Trembley

Alternate—Dr. J. E. White

The slate will be voted on at the fall meeting.

A medical clinic was held and the following papers presented:

"Bilateral Pneumothorax, with illustrative case"—Dr. F. B. Trudeau

"Congenital Atresia of the Rectum"—Dr. A. Gedroiz

"Asthma, due to unusual type of Hypersensitivity"—Dr. S. Wolfson

"Cardio Roentgenographic Study"—Dr. Brumfiel, Dr. Schwartz

"Treatment of Eye Injuries"—Dr. R. Beck

Herkimer County

THAT THE TOWN OF Herkimer will not accept a proposal made several weeks ago by ten physicians to provide medical and surgical treatment for relief clients of the town at a cost of \$12,000 a year was indicated at a meeting of the Town council, when there was read a letter from the executive director of the Emergency Relief bureau which stated that the state would not reimburse any portion of such an expenditure.

The plan of the doctors provided that the ten doctors of the town would care for all medical and surgical patients on relief with five doctors subject to call each month at a fee of \$200 each for the month.

Five doctors would provide this professional service one month then the other five would be back on call. Thus, over a year's period, each doctor would receive \$1,200.

The fact that the state TERA would not

be likely to approve such a plan, on the ground that the fees would be excessive, was disclosed in a letter from William F Jerome, executive director of the Emergency Relief bureau of the county

The only action the council took in the matter was to order Mr Jerome's letter received and filed

At present the doctors are paid fees charged for each individual case handled and the TERA reimburses the town forty per cent of the cost for medical and surgical treatment. The town has the authority to establish any system of paying doctors that it wishes, but the TERA had the authority to grant or decline to grant reimbursement. It was evident that the councilmen were not disposed to accept the doctors' proposal, when such a step would mean that no state reimbursement would be given by the TERA

Hospital bills for welfare clients are not reimbursable and the entire expense must be borne by the town

Madison County

THE WOMEN'S AUXILIARY of the Madison County Medical Society met at Hotel Oneida on June 17. Dinner was served. Reports of delegates who attended the recent state meeting in Rochester were read.

Montgomery County

THE THIRD LECTURE of the postgraduate course of the Medical Society of the County of Montgomery was held in Amsterdam on June 3. Dr James K. Quigley spoke on "Delivery Room Problems." At the fourth lecture, on June 10, Dr Ward Ekas discussed "Prenatal and Postnatal Care." At the fifth lecture, on June 17, Dr Edward C. Hughes spoke on "Toxemias of Pregnancy."

New York County

DR JOSEPH JORDAN ELLER has been appointed Attending Dermatologist to the City Hospital of New York

DR J. EPSTEIN, who in 1932 introduced gold tribromide in the treatment of pertussis, has now introduced gold and sodium tetrabromide in the treatment of epilepsy

Niagara County

A SUMMER RECREATIONAL meeting of the Niagara County Medical society will be held in August, it is announced, but no further business meetings will be held until

September. At that time, Dr Robert S. Dinsmore, of the Cleveland clinic, will address the society

Oneida County

DR H. N. SQUIER scored a hole-in-one at Teugega Country Club on June 17. It was the first ace of the physician's golfing career and is believed to be the first scored in the Rome-Utica area this season

Onondaga County

THE SECOND ANNUAL dinner dance of the Women's Auxiliary to the Onondaga County Medical society was held at the Skaneateles Country club on June 24. The afternoon was devoted to golf, bridge, and water sports. In the evening a skit was presented by a group of members

COUNTRY DOCTORS in Onondaga County will no longer have to make long trips into Syracuse day or night in order to deposit culture tubes and obtain sera if members of the Board of Supervisors approve a scheme already adopted by the county society. The plan will probably call for some sort of collection of specimens in the rural communities as is done daily in all parts of the city

TWO YEARS' TRIAL of the plan calling for an Executive Secretary to handle the affairs of the county society was voted at the May meeting held in the University club. Dr Gordon D. Hoople as chairman read the enthusiastic report.

"From a perusal of the report," says the county society's *Bulletin*, "one would gather that he must be an unusual young man. He should be college bred, but not medicated, young, presentable, a good speaker, able to entertain the ladies, a writer of no mean ability, and able to supervise all society publications—able to serve the society continuously, attend all meetings after arranging them, able to make a good appearance on the radio, contact the newspapers, meet the mayor, keep in with school authorities, welfare groups, social agencies, and so on." The salary mentioned is \$1500.

DR W. CLINTON KELLOGG, one of the oldest medical practitioners of Syracuse at the time of his retirement in March, died on May 31 at his home. He was seventy-seven years old and had practiced in Syracuse fifty-three years

Ontario County

DR JOSEPH GREENE, in charge of chest x-ray work at Strong Memorial Hospital and associate radiologist at Rochester Gen-

eral and Monroe County Hospitals, was the speaker at a monthly meeting of Canandaigua Medical Society on June 10 "Differential Diagnosis of Chest Conditions by X-ray" was the subject. Dr Robert M Ross was host at dinner preceding the business meeting and program

Queens County

THE LONG ISLAND CITY Medical Society held an outing, golf tournament and dinner at the North Hills Country Club, Douglaston, on July 1

Rensselaer County

DR. STEPHEN H CURTIS is the new president of the Alumni Association of Albany Medical College. He was installed at the annual meeting and banquet of the Alumni

Rockland County

A LUNCHEON AND SPECIAL meeting of the Woman's Auxiliary of the Rockland County Medical Society, at which several members of the State board were guests, was held in New City on June 16

Mrs Alexander of Selman, president-elect, gave a report of the Rochester convention. Mrs Albert Barker, Jr, gave a talk on nutrition. Mrs John Bauer, past state president, spoke on the work of the Auxiliary. The Rockland County branch has thirty-six members

Schenectady County

THE WOMAN'S AUXILIARY of the Schenectady County Medical Society held a luncheon meeting on June 15 Mrs John L Bauer, one of the directors of the State Auxiliary, was present. Mrs Isaac Shapiro and Mrs F Leslie Sullivan gave reports on the New York State convention at Rochester

Steuben County

THE STEUBEN COUNTY MEDICAL SOCIETY met at the Veterans' Facility in Bath on June 10 at a luncheon as guests of the staff of Maj J A Barker, chief of the Veterans' hospital. The program included papers on medical problems by Dr Hayward Hopkins and Dr Samuel Kahlstrom, Dr Chester Sturges, Dr Valentine Ujhely, and Dr H Bach of the Veterans' Hospital. Dr Francis Ogg, also of the hospital staff, conducted a clinic

Suffolk County

DR ALBERT H PAYNE, of Riverhead, who

died on June 22, aged sixty-five, had practiced medicine there for thirty-five years, and was a past president of the Suffolk County Medical Society

Tioga County

MEMBERS OF THE TIOGA COUNTY BAR Association and the Medical Society of the County of Tioga, supplemented by guests recruited from the ranks of local undertakers and newspapermen and from the staff of the Robert Packer Hospital at Sayre, on June 2 enjoyed the first annual dinner-meeting of the two organizations. About fifty-five were present. Attorney John T Gorman, of Owego, president of the Tioga County Bar Association, introduced Dr Louis D Hyde, of Owego, president of the Medical Society of the County of Tioga, who stated that the members of his organization were deeply appreciative of the honor and courtesy extended to them in having been asked to play the part of co-hosts and fellow guests on such an occasion. The guest speaker was Dr Rene Brequet, physician in charge and Psychiatrist at the New York State Reformatory at Elmira, who spoke on his work there

Wayne County

A JOINT MEETING AND DINNER of the Wayne County Bar Association and Medical Society was held in Newark on June 22. Dr Floyd Winslow of Rochester, former head of the New York State Medical Society, spoke on "Malpractice." Following the banquet the combined groups visited the new quarters of county medical laboratory at the State School

Westchester County

THE WESTCHESTER COUNTY Medical Society has expressed a further interest in a movement to enlist support for voluntary health examinations, for domestics and other persons as well, says a New Rochelle paper. The society has stated that it will "assist any responsible civic organization which chooses to initiate an educational campaign for voluntary examination of all persons who come into intimate contact with children"

The society has urged that interest be maintained in efforts to have health examinations taken by all persons. The doctors say they are willing to support a workable voluntary plan but they indicate that they, themselves, do not want to take the leadership lest the motive of the effort be misunderstood

Hospital News

Give the New Interns a Hand

HUNDREDS OF MEDICAL SCHOOL graduates are now entering the hospitals of New York State as interns, and it need hardly be said that in the coming weeks and months they will need the friendly counsel and help of the older men on the staffs to "get off on the right foot" and find their places in the hospital routine. A right or wrong start means much.

The hospital and the staff should not permit the intern to just float along and expect him to work out his own salvation, remarks the *Ohio State Medical Journal*. He needs the help and counsel of those with experience and wisdom. He deserves assistance, especially at a time when he is getting his first baptism of actual everyday, routine clinical work. Examples should be set by the older men which will be to his advantage and not give him a misconception of accepted procedures and fundamental ethics.

The intern year is the most important year in the life of the industrious, progressive, and dependable graduate in medicine, believes the editor of *Hospitals*, official organ of the American Hospital Association. The young M D is earnest in his desire to round out the theory he has been taught by its practical application at the bedside.

The intern's successful intern year, according to this authority, depends upon three things.

First, the interest of the hospital and its administration in his progress, in making available its diagnostic and therapeutic equipment for his use, as he needs it and under proper supervision.

Second, the interest and counsel of the members of the staff to whose services he may be assigned, in explaining the significance of pathology found, in teaching him the application of diagnostic procedures, and by showing a sympathetic and helpful interest in his study progress.

Third, his application to the work allotted him during his intern year, and the sincerity of the effort put forth to learn everything that will help him when he engages in private practice.

The hospital superintendent can assist the intern greatly by taking an interest in the intern's welfare and comfort while he is a guest of the hospital, in receiving him cordially when he reports for duty, in meeting with the intern body informally, and in encouraging an administrative, if not a personal, friendship with him and his staff.

Many of our better hospitals view the entering intern as a potential member of their staff, and if not of their own staff, then certainly as a member of the staff of some other good hospital.

The superintendent can serve the intern well by giving one or two informal talks to the intern body on "hospital ethics," the "role of intern service in the hospital," "professional and patient relationships."

Hospitals are becoming more and more dependent upon their intern service. They can secure better service if they will take a professional and social interest in the young medical men who are now coming to them and make them feel that the hospital will be their professional home for the coming year.

A feeling is growing that the present service for interns in most hospitals does not entirely satisfy the young graduate's needs, said President Daniel C. Patterson, of the New England Surgical Society, in his presidential address. And in confirmation he quoted Dr. Hartwell as saying:

"We are fully aware that in many instances the internships in our hospitals, which represent the second step in education, are of far less educational value than they should be. In fact, it has been said by one of our most eminent undergraduate educators that in many instances the young doctor has lost something of great value at the termination of his internship which had been in his possession at the time of his graduation. He referred to the painstaking care with which the student approached any problem, scientific or clinical, which had been inculcated into him in his student days. With the loose, hurried, unconsidered methods employed in some of our hospitals, the intern adopts short-cuts and less orderly thinking than has been his previous habit."

"Shocked Back to Sanity"

REPORTS THAT TWO Rochester hospitals had restored eight mental cases to sanity out of ten subjected to the newly devised insulin treatment has raised hopes of psychiatrists that hundreds of dementia praecox sufferers may literally be "shocked back to sanity," says an Associated Press dispatch.

The new treatment, undertaken in State and Strong Memorial hospitals, under the direction of the State Department of Mental Hygiene, was characterized by two hospital executives as "highly encouraging."

It consists, the physicians explained, of injections of doses of insulin which produce a reaction of shock in the patient.

Strong Memorial, disclosing for the first time that it is working in this field, reported two successes to its credit with the first three patients. The patients have returned to their families and the third is showing improvement, the hospital officials said.

At the State Hospital Dr. John L. Van de Mark, superintendent, confirmed reports of unexpected success with six of that hospital's first seven cases.

"We are apparently beyond the experimental state," he added. "The big question is the permanency of the cures, and time alone will tell this."

Dr. Van de Mark made it clear that while six out of seven appears to be a sensational success ratio, this will by no means continue to hold good. This, he said, is because in the first group were the best suited patients available—young, robust and recent cases.

Hospital executives pointed out that relatives and friends of mentally unbalanced persons should not permit their hopes to skyrocket because of publicity given this new and radical type of treatment.

Factors that must be considered, they said, are (1) Limited ability to carry more than a certain number of cases. (2) That the treatment can be used in no more than twenty-five to twenty-seven per cent of admissions. (3) The profound danger that exists for the patient, a danger that is an unavoidable part of the treatment.

The New York State Department of Mental Hygiene is now using insulin shock treatment in all State hospitals, including Rochester's. Before treatment began, the department arranged to have representatives of each State institution attend a six-weeks' course under Dr. Manfred Sakel, a young Vienna psychiatrist credited with discovering and pioneering in the treatment of victims of schizophrenia or split personality.

Newsy Notes

"MORE THAN 300 HOSPITALS are already making use of air-conditioning, with more equipment being installed every month," says an authority in one of the large companies. "Most popular places for installations have been in the operating rooms, in nurseries for premature and for normal babies, in oxygen therapy chambers, heat therapy rooms or cabinets, and allergic wards—wherever certain constant temperatures and humidities are most greatly needed."

AN AVERAGE OF twenty-five hospital beds from the New Rochelle hospital are out on loan at all times in private homes of New Rochelle, Larchmont, and the Pelhams. The average length of loan is three weeks. The hospital delivers and collects the beds without charge. It follows the same practice with wheel chairs, stretchers, and many other types of hospital equipment.

THE PRESBYTERIAN HOSPITAL of New York has purchased the Washington Heights property of the New York School for the Deaf in one of the largest transactions closed on Manhattan in the last ten years.

The property, which is on Riverside drive at 165th st., occupies approximately seven acres, with a frontage of 640 feet on Riverside drive, making it one of the largest unimproved properties under one ownership left on the island of Manhattan and the only one of any such size on Riverside drive.

Its purchase by the hospital was made possible by the generosity of an unnamed friend, and the fact that the School for the Deaf has purchased a 76-acre tract in the Town of Greenburgh, adjoining White Plains, N. Y., where it plans to build a new and more modern group of institutional buildings.

The Heights property is assessed at \$1,775,000. The hospital, it is understood,

has no plans for immediate improvement of the newly-acquired land although it undoubtedly will be used later to meet expanding building needs

A LAW WAS PASSED IN France in 1936 according to which a salaried employee is obliged to work only forty hours a week. The application of this law to commercial organizations has taken place at a far more rapid rate than was generally thought, resulting in innumerable protests on the part of employers. March 22 a decree was issued by the president of the republic, in accordance with a motion of the minister of labor and approved by the cabinet, extending the new law to all public and private institutions engaged in the care of the sick or mentally incapacitated. The French Private Hospital Association is sending to the government a resolution of protest against the application of the forty hour week to private institutions.

PLEDGE MADE TO A HOSPITAL IS BINDING

A PROMISE TO CONTRIBUTE \$5,000 to Beth-Israel Hospital in New York City was declared binding and enforceable by the Appellate Division in a four-to-one decision on June 18. Previously Supreme Court Justice Philip J. McCook had ruled the pledge unenforceable because it was made without receipt of any consideration.

The agreement was to pay the \$5,000 in four equal annual installments "to aid and

assist the Beth-Israel Hospital Association in its humanitarian work." The pledge was assigned by the hospital to the I & I Holding Corporation, which brought suit when the lawyer failed to pay.

"The subscriber who fills in a subscription blank and the charity promisee do not contemplate a bargain in the mercantile sense," Justice Albert Cohn said in the majority opinion. "Nevertheless, where the subscriber agrees to pay for a certain purpose and the promisee thereafter spends the money for that purpose both intend a binding pledge and the former should be compelled to live up to his promise. The acts of the hospital here in reliance upon the pledge made by the defendant as alleged in the complaint furnished the consideration for the promise to pay and created the promissory estoppel."

Justice McCook in his decision held that the court in determining whether or not there was consideration could look no further than the pledge itself, but the Appellate Division ruled otherwise.

"We conclude," Justice Cohn said, "that the court is not limited to the language of the subscription agreement for the purpose of ascertaining the consideration for the promise of defendant to pay."

Presiding Justice Martin, who wrote a dissenting opinion, agreed with Justice McCook in holding that the pledge was not legally binding.

He suggested, however, that the time might be ripe for the Legislature to declare that a consideration is not necessary to make a charitable pledge enforceable.

Improvements

THE NEW \$100,000 WING of St. Joseph's Hospital at Far Rockaway, housing the pediatric and maternity wards, was dedicated on June 6.

THE NEW CHAPEL at Gowanda State Hospital was dedicated on June 8.

HERKIMER MEMORIAL HOSPITAL is contemplating the addition of a new wing on the east front to correspond with the one on the west. The present bed capacity is only thirty, while the average number of patients last year was twenty-nine, a number which sometimes rose to forty-five, and was generally nearer forty than thirty. The new

wing would accommodate twenty more beds, and would allow the segregation of maternity cases, something not now possible. George J. Sluyter, president, estimates the probable cost of the construction between \$30,000 and \$40,000.

THE RAISING OF \$6,000 for the enlargement of the obstetrical division at the Fox Memorial Hospital at Oneonta and for the purchase of the most modern equipment, instruments and supplies, has been undertaken by the Junior board of the institution. In 1927 the hospital served seventy-one cases in the maternity ward, in 1936 there were 219 cases, over three times as many, and

already this year the number of cases has increased nearly ten per cent for the five months. The problems of the trying conditions this increase has brought have been met by most unusual effort and sacrifices on the part of physicians and nurses, but if allowed to continue they might ultimately affect the work of the whole hospital service.

BROOKS MEMORIAL HOSPITAL, at Dunkirk is renovating, redecorating and refurnishing all the rooms in the main building

THE LITTLE FALLS HOSPITAL is raising \$200,000 for a new addition

SEA VIEW HOSPITAL, at West New Brighton, is building an addition to the nurses' home.

LEONARD HOSPITAL, at Troy, is rebuilding its nurses' home, burned in January. It will have twenty-three single rooms, with marked changes and improvements

THE ELLIS HOSPITAL at Schenectady will launch a \$700,000 building fund campaign for a new building with 100 additional beds, extending the present space in which the laboratory is located, establishment of a new X-ray department and building a kitchen to meet the needs of the enlarged plant. The hospital last year had an average of 227 bed patients daily, in addition to 6,000 outpatients who were treated in the hospital's clinics. The constant growth in the service given by the hospital has so taxed its capacity that the board of managers and the medical staff recently voted to conduct a public campaign this fall to raise the building and expansion fund

PLANS AND SPECIFICATIONS for an addition to the Nyack Hospital have been drawn. The addition, seventeen by forty-one feet, will be of fireproof construction at the front of the building. The first floor will be a lobby and the second floor will contain an apartment for the superintendent, consisting of a living room, bedroom, and bathroom.

Under a separate bid, another addition, fifteen by seventeen feet, will be erected. This will contain a room for the board of managers and a doctors' lounge

Events

TRINITY HOSPITAL, in Brooklyn, celebrated its tenth anniversary with a dinner, entertainment and ball at the Waldorf-Astoria on June 24

DR. ABRAHAM BERGER, chief of the Unity Hospital Dental Clinic in Brooklyn, who recently completed ten years of service at the institution was given a dinner by more

than fifty of his professional associates and friends in the Half Moon Hotel, Coney Island, on June 3, in recognition of his achievements

MR. MAX DE KAYE, who has been superintendent of Beth El Hospital in Brooklyn for ten years, was feted at a luncheon on June 13 by the board of directors

At the Helm

THE FOLLOWING HOSPITAL OFFICIALS HAVE BEEN CHOSEN

Miss Isabelle Cameron, to be superintendent of the Monticello Hospital

Dr James M Blake, to be superintendent of the Glenridge Sanatorium at Schenectady, succeeding Dr James C Walsh, who recently became superintendent of the Nassau County Tuberculosis Hospital at Farmingdale, L. I

Dr J R Clemmons, to be director of Roosevelt Hospital in New York City, taking office in the fall

Marshall Field, to be a director of Huntington Hospital, to fill the vacancy caused by the retirement of A G Milbank

Mrs Louis Wolner, to be president of the Homer Hospital Aid, at Cortland

Mrs George H McFarland, 3d, to be president of the woman's auxiliary of the Mary McClellan Hospital at Cambridge.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Violation of Harrison Narcotic Act as Involving Moral Turpitude

The highest court in one of the western States very recently handed down a decision upon the question of what crimes involve moral turpitude so as to subject a physician to disciplinary proceedings.*

The physician involved was a certain D who had been previously indicted by a Federal Grand Jury and convicted upon charges of a violation of the Harrison Narcotic Act. He had been sentenced to serve a prison term of fourteen months and in addition to pay a fine. The indictment upon which D was convicted charged him with having sold morphine to an addict, not in the course of his professional practice, and without a written order to the addict on the blank for the purpose supplied by the Commissioner of Internal Revenue. An appeal was taken from the conviction and it was affirmed.

The Harrison Act under question, it should be noted, is considered a tax measure, but is a tax measure with a broader object behind it. One Federal Court in commenting upon the Act has said:

The act is ostensibly a revenue measure and within limits the courts must recognize it as such. At the same time any one with sense enough to be at large without a keeper knows the revenue feature, which possibly returns cents for dollars spent in administration is but a fiction and device to enable Congress, otherwise disabled to suppress opium traffic and use, to hinder and obstruct such traffic and use so far as may be done incidental to exercise of revenue power.

Proceedings were instituted before the State Board of Medical Examiners against D for the purpose of revoking his license to practice medicine. The charges first specified that he had been guilty of unprofessional conduct as a physician and surgeon in that he had dispensed drugs to an habitual user of such drugs without intending to cure the habitual user of the use of such drugs. The charges in addition specifically recited the fact that D had been indicted, convicted and sentenced for a violation of the Harrison Narcotic Act, and further that the charge and offense upon which D was convicted involved moral turpitude, and that he

was guilty of unprofessional conduct as defined in the State statute regulating the practice of medicine.

The State statute under consideration in one section empowered the Board of Medical Examiners to issue licenses to practice medicine in the State. Another section of the same statute provided that a person who had been guilty of unprofessional conduct should not be so licensed, and that when a license holder is guilty of unprofessional conduct his license should be revoked by the Board after due hearing. The statute also defined the expression "unprofessional conduct" to include among other things the procuring of a criminal abortion, improper advertising, habitual intemperance in the use of alcohol or drugs, and the "conviction of any offense involving moral turpitude, in which case the record of conviction shall be conclusive evidence."

The physician appeared with counsel before the Board of Medical Examiners for the hearing of the charges. The prosecution introduced evidence both oral and documentary to support the charges. D did not deny that he had been so convicted by the Federal Court nor did he give any testimony or offer any evidence, but objected to all the evidence against him on the grounds that the charges failed to state any statutory grounds for the revocation.

The Board ordered that D was found guilty of unprofessional conduct and that his license to practice should be revoked. He thereupon instituted *certiorari* proceedings in the Superior Court to review the order, and from a judgment of that Court affirming the action of the Board he took the matter to the highest State Court.

The primary question for consideration upon the appeal was the interpretation of the term "moral turpitude" as expressed in the statute, and whether a conviction under the Harrison Act should properly be held to evince moral turpitude. The Appellate Court ruled that the revocation of the license should be affirmed, thereby deciding that such a conviction did involve moral turpitude within the meaning of the act regulating medical practice. In so ruling the Court said in its opinion:

Just what crimes involve moral turpitude is not always easy to say. Generally speaking,

* *DuVall v. Board of Medical Examiners*
66 Pac. (2nd) 1026

those crimes that are *malum in se* involve moral turpitude while those that are *malum prohibitum* do not. But this is not always so. For instance, assault and battery is *malum in se*, but rarely involves moral turpitude, while the sale or dispensing or prescribing of narcotic drugs, except for medicinal use, and under strict surveillance, does involve, as we think, moral turpitude, although *malum prohibitum* only. One of the great evils of the day is the consumption of narcotic drugs. Because so many persons become addicts, most of the states, if not all of them, have enacted laws restricting the right to dispense or prescribe such drugs to registered pharmacists and physicians for medicinal purposes only and inflicting very severe penalties for their violation. While the United States under principles of police power cannot take control of narcotic drugs, and regulate their disposition and use, it has under the taxing power made the traffic in such drugs more difficult.

Mr. Newell in his work on Slander and Libel (4th Ed.) Sec. 32, says "Moral turpitude may therefore be defined as an act of baseness, villainess or depravity in the private and social duties, which a man owes to his fellow-men, or to society in general, contrary to the accepted and customary rule of right and duty between man and man."

If there is any one who is to be pitied, it is the addict of habit-forming drugs of the narcotic kind. He is usually a hopeless loss to society. Not only that, but he is a real menace. He will do most anything to secure the drug to satisfy his cravings and under its influence commit most desperate crimes. No one knows this better than the members of the medical profession, bound by their honor and the Hippocratic oath to the highest ideals in their relation to society and especially those seeking their advice and help. When one of these has been convicted of violating the Harrison Narcotic Act we think it safe to say he is guilty of "an act of baseness—contrary to the accepted and customary rule of right and duty between man and man" as manifested by legislation by most of the states and the United States and by common consent.

Needle Breaking Case

A middle-aged woman who was suffering from tuberculosis had been under the care of a physician, who for sometime had been regularly administering to her certain injections into the pleural cavity. On one occasion, when the patient came for her injection, the doctor after sterilizing the area inserted between the eighth and ninth ribs a two inch, twenty gauge needle. After the needle had been so inserted, but before he was able to attach the tube thereto, without apparent cause the needle snapped. The doctor found that about two-thirds of the needle remained in the patient's chest. The doctor made no attempt at the time to remove the needle but promptly had the pa-

tient taken to a hospital for x-rays. He called into consultation a surgeon and it was decided that the needle was in the chest cavity where it would be inadvisable to attempt a removal. Sometime thereafter a malpractice action was brought against the doctor charging that he had negligently broken the needle and had negligently permitted it to remain within the plaintiff.

The case came on for trial as a non-jury case and the plaintiff offered no expert testimony to establish negligence on the part of the defendant in breaking the needle. Her theory seemed to be that the loss of a portion of the needle was of itself evidence of lack of skill on the part of the defendant. The defendant's proof showed that he did what was usual in connection with the treatment of the patient and that sometimes needles break regardless of the fact that due care and skill was used throughout the treatment. The plaintiff undertook to prove that at the time the needle was inserted that there was another doctor present in the room to whom the defendant was talking.

The court ruled that the defendant was entitled to judgment dismissing the complaint on the merits as plaintiff did not establish a course of action.

Treatment of Styte

A man consulted a physician who specialized in the treatment of eye, ear, nose, and throat diseases for the purpose of having his eyes fitted with glasses. After the glasses had been so furnished, he returned to the doctor complaining of a styte in his right eye. The doctor decided that the styte should be opened and using a sterile knife under the usual aseptic precaution lanced the styte and cleaned the same. He gave the patient a preparation of silver which he directed should be dropped into the eye, two drops every two hours. The patient was also told to return the following day for further treatment. The patient, however, failed to return as directed.

The next the doctor heard from the man was when an action was instituted against him charging malpractice. The plaintiff claimed that the defendant had operated upon the eye and had permitted the eye to be left without applying any antiseptic as a result of which an infection had been caused which extended throughout the eye and continued as a painful condition for over a month. He did not claim, however, any loss of vision or any permanent injuries.

When the case was about to be reached for trial, plaintiff's attorney consented to discontinue the action thereby admitting he was unable to establish a cause of action against the defendant doctor.

Across the Desk

Father now the "Problem Child" of the Family

FATHER SEEMS TO BE CROWDING the baby out of its long-held place as the chief health-worry of the family. The infant scourges of years ago are yielding to science, but, as they decrease, the ills at the other end of the scale grow more savage and threatening. Diphtheria, typhoid, tuberculosis, the intestinal infections of childhood, all are greatly diminished, the degenerative ills of age, arteriosclerosis, high blood pressure, cardiovascular-renal diseases, cancer, diabetes, all are on the increase.

"Old-age security" is on the wrong track, as embodied in legislation passed at Washington. Real security is not to be had by deductions from pay envelopes or contributions by employers. For old age is being attacked by foes that will yield to only one defender—medical science. The family physician is finding the character of his practice changing. He is being called for fewer and fewer cases of diphtheria and cholera infantum, and for more and more cases of illness peculiar to life's afternoon and evening.

Life-insurance companies, too, do not insure life. They only insure that the widow will receive a specified sum when her husband dies. Life is insured, if at all, by medical science, which discovers the evil forces that are threatening life and defeats them. That is real insurance of life, not insurance of a postmortem consolation payment.

Give the Seeds of Death a Crop Failure

A Latin poet said that "we do not wholly die." That is, we live on in the hearts and fond memories of our friends, or in the resounding echoes of fame, as the poet himself still lives. It might also be said that we do not die all at once. We begin to die, little by little, many years before we close our eyes for our final sleep, and it is the doctor's task to detect the insidious approach of mortality, as it creeps into this or that avenue of the organism, and to put it to rout. A poet might say that we have within us the seeds of death from the day we are born, as we

are all mortal, but it is a hard, cold fact that the fatal seeds are implanted in life's garden at some time, soon or late, and it is the M.D.'s job to give them a crop failure.

A great difficulty with father as the new "problem child" is that he disregards health's danger signals. He runs recklessly past the red lights. When baby has a pain, the whole neighborhood gets the news, but when father has an ache, he says nothing about it. That is what gives value to a series of advertisements that are being run in the popular magazines by a leading pharmaceutical firm, frankly addressed to "the man of 50," and advising him to see his family doctor and have an examination. They are based on a statement made shortly before his last illness by Dr. Lafayette B. Mendel, Sterling Professor of Physiological Chemistry at Yale and for eighteen years a member of the Council of Pharmacy and Chemistry of the AMA. He said

"Something should be done about the man of 50. Nobody seems to be paying much attention to the increasing 'degenerative' conditions among middle-aged men. All these conditions—heart disease, kidney trouble, hardening of the arteries, high blood pressure, diabetes—may be alleviated. The problem is to get men to go to the doctor *in advance* of trouble. But it is customary for men not to do anything about their health until definite symptoms appear. We ought to change that."

With this key truth as a text, these advertisements by Squibb tell the man of fifty that

No man can be his own best friend after fifty—he should share the responsibility with his physician. So see your doctor and ask for a complete check-up—even if you feel perfectly well. It takes very little time, and by following his advice, by reducing your "speed," you will find those higher hills easy to take.

Once you have started, above all continue to see your doctor at reasonable intervals. That is the best way to be sure of getting the most out of your life after fifty.

"Sudden Deaths" are not Sudden

The sudden death of the administration leader in the Senate a few days ago gives point to this advice. Such a death is not "sudden." Dr. Charles H. Mayo, in *The Rotarian* for June, remarked on a similar case "He didn't die suddenly, he was years in dying. Years ago his physician, if given the opportunity, might have discovered the damaged heart which probably he had had since some infectious disease or infected teeth or tonsils in childhood. Early detection would have added happy, useful years to his life."

"The longer the belt line, the shorter the life line," is the crisp rule laid down by the *Statistical Bulletin* of the Metropolitan Life Insurance Company. Life insurance companies, we are told, pay a lot of attention to the waist measure. Insurance study shows that men who are overweight by thirty-five per cent or more have a mortality over 1½ times that of average-weight men and the greater the overweight, the greater the mortality. Of all the types of overweights "the pot-bellied variety is the worst," we are informed frankly. An imposing list of degenerative ills is found to accompany overweight.

High blood pressure, for example, is over 2½ times as common among overweights as among persons of average weight. Albuminuria

and glycosuria in significant amounts are nearly twice as frequent. The specific hazards of overweight include most of the important diseases of adult life, especially the cardiovascular-renal diseases, which are responsible for an increasing proportion of the death toll today. Thus, the death rate of overweights from heart disease and from cerebral hemorrhage is 1½ times that of average weights and nearly twice that of underweights. For angina pectoris, the difference is even larger. The mortality of overweights from this condition is more than twice that of average weights and 2½ times that of underweights. Bright's disease exacts a death rate among overweights 1½ times that among average weights, and 2¼ times that among underweights. The most striking difference of all is found for diabetes. The death rate of overweights from this disease is 2½ times that among average weights and four times that among underweights.

The question used to be "How much does the baby weigh?" Now a more important query is "How much does father weigh?"

The splendid extension of the span of life has brought the family breadwinner into the zone where he is endangered by formidable diseases that we may perhaps defeat if we can only take them in time. What is needed right now is a campaign to awaken the father to the realities of the situation and to show him that loyal friends stand ready to give him a helping hand.

Use of Sulfanilamide in Gonorrhea

THE "FIRST SATISFACTORY TREATMENT" for gonorrhea is the description given by Dr. Frederick A. Reuter, Professor of Clinical Urology of the George Washington University School of Medicine, in a paper describing the use of sulfanilamide. "Its effect is rapid when effective," he declares, "and it has been successful in producing at least a clinical recovery in 90 per cent of our test series of 100 cases." His paper appears in the May issue of the *Medical Annals of the District of Columbia*, and almost simultaneously, on May 29, a paper was published giving similar conclusions in the *Journal of the A.M.A.* (See page 1393, this issue of the JOURNAL.)

We are told in the latter paper that because of the close biologic relationship between the meningococcus and the gonococcus John E. Dees and J. A. C. Colston Baltimore, investigated the effect of oral administration of sulfanilamide in nineteen

cases of gonococcal infection seen in the Brady Urological Dispensary of the Johns Hopkins Hospital. With a few exceptions, all patients received, in four divided doses a day, 48 gm of sulfanilamide daily for two days, 36 gm daily for three days, and then 24 gm daily for from four to eight days.

Interesting Results

The active urethral discharge disappeared in three cases in one day, in seven cases in two days, in two cases in three days, in two cases in seven days. In one case it disappeared in four days to recur slightly on the fourteenth day and again disappeared on the sixteenth day. One patient was treated for two days with sulfanilamide but failed to return until three days later. The discharge had continued during this time. The drug was again administered for two days but the patient did not return until the

twentieth day, at which time the discharge was still present and positive for gonococci. The drug was again administered and the discharge disappeared and the smear became negative for gonococci in the ensuing three days and has not recurred to date. In two cases the discharge is still present ten and twelve days respectively after the beginning of treatment.

One patient, with chronic anterior and posterior urethritis, subacute prostatitis, subacute right epididymitis and acute left epididymitis had no urethral discharge, but gonococci were demonstrated on smear and culture from the urine. The organisms disappeared three days after the institution of treatment, and there had been marked diminution in the swelling of the left epididymis. When seen last on the fourteenth day after the institution of the treatment, the patient was free from symptoms, there was no urethral discharge and the urine was clear in three glasses. Prostatic secretion showed from six to eight white cells per high power field. Stained smears from the urethral discharge and centrifugated urine became negative for gonococci in from two to twenty-three days. In one case smears became negative on the ninth day, positive on the fourteenth day and again negative on the seventeenth day. In three cases gonococci are still present after eleven days.

Cautions and Dangers

Symptoms of burning and frequency disappeared in from one to eight days. Symptoms of slight dizziness and lassitude occurred in four cases with the initial larger doses but disappeared when the amount of the drug was reduced. In several instances it was noted that, as the urethral discharge

began to disappear, the gonococci were found to lie extracellularly, with little or no evidence of phagocytosis by the leukocytes. Immediately on the complaint by the patient of lassitude or dizziness, the dosage must be reduced or the drug discontinued completely. Should symptoms persist, a complete blood study should be done. Their use of sulfanilamide in the treatment of gonococci infections has led the authors to believe that this drug will prove of great value when large numbers of gonococci infections can be closely followed, so that an accurate evaluation of sulfanilamide in the treatment of gonococci infections can be determined and the optimal dosage and possible deleterious effects further studied.

Certain dangers are associated with the use of sulfanilamide, observes Dr. Reuter in the *Medical Annals of the District of Columbia*. It was at first believed to be nontoxic, but with the great increase in its use, reports have shown that it should be used with caution. Since it will probably come to be used universally for the treatment of gonorrhea, one can readily visualize its uncontrolled abuse because of the advice one patient with gonorrhea passes to a fellow-sufferer, because of nation-wide publicity given the preparation under trade names, and because of the ease with which it can be purchased from any drug store counter without a prescription. It can be bought indiscriminately at any pharmacy and used without control. Until such a time when proper steps shall have been taken to protect the public from its harmful effects it rests with the medical profession to bend every effort to assume that duty. This can be accomplished by placing on the prescription the words "Do not refill."

THE GOLF TOURNAMENT IN ROCHESTER

On May 27 the championship of the State Society was won by Dr. W. E. Pelow of Syracuse, with a score of 81. Dr. Pelow was awarded the beautiful solid silver trophy presented by Dr. Floyd S. Winslow. Dr. H. H. Hopkins of Rochester, the runner-up with a score of 86, was awarded the championship of the Inter-City Academy of Medicine League. The trophy was a beautiful solid silver one. Dr. Augustus B. Wadsworth of Albany won the Senior's championship with a score of 92. He was awarded the beautiful trophy presented by the Paine Drug Company of Rochester. The left-handed golfers' championship was won by Dr. Balfour of Toronto.

The team match was won by the Roches-

ter Academy of Medicine, with the Buffalo Academy of Medicine in the second place. The Toronto Academy of Medicine and the Hamilton Academy of Medicine occupied third and fourth places, respectively. The Rochester Academy of Medicine therefore, becomes the possessor of the Josiah K. Lilly Trophy for the second time. This competition was inaugurated in 1931, at which time it was won by the Rochester Academy of Medicine. For the next four consecutive years it was won by the Toronto Academy of Medicine. In 1936 it was won by the Hamilton Academy of Medicine. The contest for this trophy is held yearly and is open to academies of medicine in New York State and Canada.

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

REVIEWED

Nutritive Aspects of Canned Foods American Can Co.

A second book containing scientific facts on commercially canned foods has recently been published by the American Can Company, compiled by the Nutrition Laboratory in the Research Department of the Company. This book has been prepared for doctors and scientific workers with canned foods. The earlier book, "Facts About Commercially Canned Foods," was published last year.

The book is a general summary of facts about tin containers and canned foods. It

is divided into two sections. The first deals with the preservation of foods, dietary requirements, the mineral and vitamin conservation in canned foods, infant nutrition, and the safety of canned foods under modern methods of packing. Section two takes up the manufacture of the cans, including the tinplating, enameling, and a description of can sizes. It also discusses the canning procedure from the raw materials through the sealing of the cans and the heat processing.

The back of the book contains an appendix of reference tables of all kinds. There

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St., N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

are charts on human energy expenditures, dietary requirements, mineral and iodine content of various foods, and analyses of canned foods of many kinds. A bibliography contains an appendix of references to the more complete works on each phase of the industry as well as the general texts used in preparation of the book.

A Hand-Book of Ocular Therapeutics. By Sanford R. Gifford, M.D. Second edition, thoroughly revised. Octavo of 341 pages, illustrated. Philadelphia, Lea & Febiger, 1937. Cloth, \$3.75.

This compact and useful book has been expanded by some 70 pages in the second edition. New drugs and procedures have come into the field since the first edition and these are discussed and appraised. A number of pages is given to the use of vitamins and glandular extracts.

New material is added to the chapters on physical therapy and dermatitis, as well as to that on keratitis, and a chapter has been added on diseases of the orbit and on retinitis pigmentosa and myopia. Illustrations have been increased in number and clarity and the format has been improved by the use of bold faced type in subheadings and by the frequent use of italics for emphasis of important points.

E. CLIFFORD PLACE

Diseases of the Coronary Arteries and Cardiac Pain. Edited by Robert L. Levy, M.D. Octavo of 445 pages, illustrated. New York, The Macmillan Company, 1936. Cloth, \$6.00.

There is need at present for us to pause and take stock of the state of knowledge of diseases of the coronary arteries. Information has been accumulating so fast that physicians feel the need of some volume to which they can turn as an authoritative reference book on all phases of this subject. This they now have in *Diseases of the Coronary Arteries and Cardiac Pain*. Excellent chapters on all phases of the subject are written by outstanding authorities.

The seriousness with which each title is discussed is worthy of more than passing comment. Fundamental principles are presented, and gaps in our knowledge especially in anatomy and physiology are clearly shown. The chapters on anatomy and physiology of the coronary arteries are particularly noteworthy. They require close reading but well repay the effort.

The section on nervous pathways concerned in the mechanism of cardiac pain is excellent and gives one a precise conception of what can be expected of each of the surgical procedures advocated to relieve anginal pain. The use and value

of the electrocardiogram is clearly expounded, particularly the interpretation of precordial leads in cardiac infarction. The reader can find helpful information on clinical diagnosis and management of coronary artery disease and cardiac infarction, and also upon the rarer affections of the coronary vessels.

This volume is heartily recommended both for the practicing physician and for students of fundamental problems of diseases of the coronary arteries.

EDWIN P. MAYNARD, JR.

The Diagnosis and Treatment of Chronic Diseases of the Respiratory Tract. With Especial Reference to the Lesions of the Trachea, Bronchi, Lungs, Pleura and Diaphragm. By Elmer H. Funk, M.D. Revised by Burgess Gordon, M.D. (Reprinted from Oxford Monographs on Diagnosis and Treatment). Octavo of 618 pages, illustrated. New York, Oxford University Press, 1936. Cloth, \$8.00.

This book covers the subject of chronic respiratory diseases in a thorough and complete manner.

As in all such work, some portions are of relatively greater value than others. Particularly excellent are those dealing with the subject "Pulmonary Tuberculosis and Its Treatment." The arrangement of the earlier chapters of the book is a little confusing, the subjects are jumped about in rather curious fashion from etiology to treatment, from thoracentesis to tuberculin reaction and heliotherapy. The technique of artificial pneumothorax is not in that portion dealing with pulmonary tuberculosis but in one of the earlier chapters, isolated. The chapters on neoplasm of the lung are excellently developed, and throughout the book are numerous clarifying illustrations.

FOSTER MURRAY

Live Long and Be Happy. How to Prolong your Life and Enjoy it. By Lewellys F. Barker, M.D. Duodecimo of 224 pages. New York, D. Appleton-Century Company, 1936. Cloth, \$2.00.

It would seem that the author in his effort to speak to the layman and the physician at the same time has missed his mark. What the trained and experienced physician has to say to his fellow practitioners is one thing, and what one should, may, and can say to the intelligent layman about medicine is quite another. This little volume very graphically illustrates the truth of this statement. It does act as an excellent guide for the doctor who attempts to explain adequately to his patients in simple language, the causes, symptoms and treatment of their diseases.

THE AIMS OF A CANCER GROUP

WILLIAM E. HOWES, M.D., *Brooklyn*

Clinical Director, Brooklyn Cancer Institute

The City of New York has seen fit to set aside The Brooklyn Cancer Institute, an autonomous hospital of eighty-five beds among the Kings County Hospital group for the study and care of the cancer patient.

While this present Institute is a newly organized unit, staffed by a representative group of Brooklyn physicians chosen by a special committee appointed by the Commissioner of Hospitals, it is in reality the result of the logical outgrowth from the already established Brooklyn Cancer Institute first organized by Dr Charles A. Brown, in the old Cumberland Street Hospital Building in 1925. From 1925 until January 1930 this old structure was maintained as the only Cancer Hospital in Brooklyn and was ordered evacuated only because it violated certain fire ordinances. While the hospital proper was evacuated, the outpatient clinic in the old building was permitted to continue its service, and through the courtesy of the Staff of the Cumberland Hospital, two wards were set aside in the newer Cumberland Hospital, some two blocks away, for cases requiring hospitalization. The fact that this Clinic grew in activity and in numbers of patients from year to year, clearly demonstrated its need. Because of their knowledge and experience, the Staff of the present institution was developed about the nucleus already established at the old clinic.

Now we who have been chosen to man this Institution have been given a rare opportunity. The City with the aid of the P.W.A. funds has presented us with a physical plant that can hardly be excelled with which to care for the City's poor, suffering from neoplastic and allied diseases. It has furnished us with the proper nursing and technical personnel, and has provided for us the special instruments for careful examination, laboratory and x-ray diagnostic facilities. We have a battery of four x-ray therapy machines and the use of emanation from the Radium Solution at the Welfare Island Cancer Hospital. The necessity of giving us a needed gram of radium element is now being considered and has been recommended to the Department of the Budget Director.

In return for these physical advantages what should the individual citizen expect? In the first place, he should expect expert careful medical and nursing care of the poor cancer patient. He should expect that this care be given not only within the limits of our personal knowledge, enthusiasm, and strength, but more than this, that it should be rendered in the knowledge of the newer and better methods of treating cancer. He should expect us to be in the position not only to distribute that knowledge to the whole community but particularly to the physicians of the Community.

Read before the interdepartmental meeting of the Cancer Units of the Division of Cancer (Ira I. Kaplan, M.D., Director), Department of Hospitals, City of New York, December 27, 1936

Now, besides the actual care of the patient, what activities should be fostered?

First Regular clinical and pathological conferences to which the physicians of the community are invited

Second Cooperation between the members of the Staff of the Brooklyn Cancer Institute and the County Medical Society (a) in order to aid in the local societies' activities in Cancer work and (b) to cooperate in lay educational movements for the discussion of cancer

Third (And of the Utmost Importance) Research Work While we are as yet in no position to do any extensive research with animal experimentation, we are, on the other hand, provided with an endless stream of clinical material, which, with the careful check of our results, using approved advanced methods of treatment, should give us the opportunity to thoroughly evaluate such methods of treatment as employed by us. This includes exacting records from the staff plus careful follow-up by a Social Service Department. This will permit the careful evaluation of surgery, x-ray, and radium therapy methods used separately or in various combinations and the careful evaluation of interstitial, intercavity radiation as compared with external radiation from different qualities of x-ray and various forms of telerradium therapy

Research in Radiology The question of the reaction of tissues to different qualities of x-ray is still a highly debatable subject. One leading radiologist boldly states and tends to prove with certain biological tests that cellular tissues respond equally to all qualities of x-ray and that similar doses will result in a given percentage of cell death, while others question whether the reaction of the cells in a complex organism such as the human body, constantly bathed in lymph with blood and nerve supply furnished from distant sources and with the different types of cells showing vastly different reactions in time and form to the x-ray, can be compared in any way with the results demonstrated in the laboratory with unicellular and simpler organisms. Perhaps the simplest variant of all—time—is still being questioned. One leading group of radiologists in this country claim that giving fifty r per min-

ute gives equivalent reactions within biological limits as compared with three to five r per minute. We all know that the leading French school has rationalized their therapy on the fact that the differential between the normal and neoplastic cells is better accomplished by prolonging the time of radiation. Another simple time relationship is the spacing of treatments. Shall the treatments be given daily, twice daily, every second or third day, weekly or monthly intervals? Shall the dose be large or small? Does radiation injure the smaller capillaries and thereby cut off the blood supply to a tumor? Are the tumor cells more sensitive to radiation during mitosis or must the cells be destroyed as by a cautery with massive doses? What happens in the tissues to produce death in a cell—must the radiation be absorbed, diffracted or is there a secondary ionization that actually results in tissue reaction or cell death? All these questions we shall strive to answer

Research in Pathology Next, let our research approach the issue from pathological angles. Broder, by his simply grouping of all types of malignancies into four main groups, mostly from a morphological angle, gave a great impetus to the value of a pathological diagnosis to the clinician. McCarthy, from the same school, however, has shown that there are some eighteen ways by which a tumor may be classified. The study of the blood supply, the comparison of the primary with secondary growth all open up great fields of research.

The pathologist, in consultation with the clinicians, should set down certain broad fields of classification. Any system should agree as closely as possible with the accepted methods of pathological classification, the pathological classification should dovetail with the clinical grouping to show the extent of involvement. In this way our records could be compared with those of other cancer centers.

Research can include the clinical classification of all patients. We all agree that a smaller solitary lesion is easier to treat than a larger lesion with multiple growths. Even the simplest lesion of all to destroy, namely the basal cell carcinoma on the skin may assume hopeless

proportions if not treated or if unwisely treated. Lesions in the esophagus, stomach, intestine, and colon have usually been present for many months before the patient reaches our institution. This classification should include accurate measurements of all surface lesions and estimation of size and shape of deeper lesions.

The simple study of the usual progress of certain types of malignancy can be further investigated, thanks to the cheerful cooperation of the gynecological, urological, and radiation services. Many of us know that the average case of cervix carcinoma is more apt to die of uremia from obliteration of the ureters due to parametrial extension rather than from other causes as hemorrhage or distant metastases. We are now attempting to coordinate the clinical, physical, and roentgenological changes in such cases and it is my impression that we may be able to find complete or partial obstruction to the ureter nearly as soon as the parametrial thickening is palpated rectally and long before any obstruction is suspected clinically.

Research in Serology may include the more careful estimation of liver damage by newer methods as has been suggested, both to determine the possibility of the progress of the disease to the liver and to determine the debilitating effects of cancer, surgery, and radiation on liver function.

Research in Diets The optimal diet for a cancer patient should be worked out. Does the cancer patient suffer from vitamin deficiency? Can radiation sickness be controlled by diet?

Research in Surgery This field is limitless and special problems will be suggested and carried out.

And so, only by cooperation between all services can a hospital of this nature function efficiently and only by frank discussion can the many problems be fairly met. Any radiologist, naturally tends to look upon the problems from the background of his personal experience. I have been fortunate in having had an ex-

perience in general practice before taking up radiology which I hope will keep my mind open to the many great advantages and achievements of skillful surgery. As a radiologist, I invite the surgeons of the staff to suggest the possibilities of different types of surgery in a broader way of dealing with groups of malignancy or in the treatment of individual cases. Recently our group of surgeons agreed that before treatment of any cases of carcinoma of the rectum, a consultation be arranged between the surgeon, internist, and radiologist, so that we may outline in a general way the broad policies of surgery or radiation to be followed in such an individual case. In that way early mobile carcinoma of the rectum would not be sidetracked into prolonged treatment with radium and x-ray when an immediate radical resection is indicated. On the other hand, such a consultation may deter the surgeon who might attempt to routinely try to remove the irremovable growth or operate on a patient who most evidently is constitutionally unfitted for such an extensive procedure.

It is the wish of the three directors* that all new cases be subjected to the same consultation as to type of therapy to be employed so that certain broad principles of procedure may be properly instituted. I am particularly interested in the treatment of breast malignancy. Here is a disease which develops in both sexes in a gland near the surface, easy to palpate, and relatively easy to diagnose. This is the place where, with full cooperation of the surgeons, we should work out a rational procedure. Certainly no startling advance has been made in our mode of surgical attack since the day of Halstead. Up to the present no startling changes have been reported following pre-operative radiation, still with certain selected cases which were given prolonged intensive highly filtered radiation malignant tumors, proven by biopsy have clinically disappeared and more extensive malignancies have retrogressed to one-third or less of their previous size.

* The Commissioner of Hospitals (Dr S S Goldwater) has ordered under General Order #277, paragraph "c" "The Directors of Surgery, Medicine and Radiation Therapy shall constitute a clinical committee to be responsible for the clinical policy in general and for the individual treatment and care of patients where the general established clinical routine fails to determine the best form and sequence of therapy for that case."

Glandular and bone metastases have been controlled. I am, therefore, making an appeal that some program be set up whereby a certain percentage of all breast lesions be treated from a radiological viewpoint (which does not omit surgery) and others treated from a surgical viewpoint, in order that we can evaluate the method best to follow.

Plan of Building

FIFTH FLOOR

General Pathological Laboratory
Conference Room
Library
Sun Porches

FOURTH FLOOR

Operating Suite
Anesthetic & cystoscopic rooms
Radium room and safe
Female Wards (small and large wards)
(Radium bomb in small ward)

THIRD FLOOR

Female Wards (two small wards and one large ward)
Two semi-private rooms
Dressing rooms
Recreation and Dining Rooms

SECOND FLOOR

Male Wards (two small wards and one large ward)

Two semi-private rooms
Dressing room
Dining Room, which is used for recreation room during day except meal hours
Social Service Office

FIRST FLOOR

Executive Offices
X-ray diagnostic rooms
X-ray therapy Department (four treatment rooms)
Waiting Room
Head Nurse's Office
Clinic Rooms (Surgery, Gynecology, Medicine, Dentistry, and GU)

GROUND FLOOR

Meeting Room for Staff and for larger groups
Locker and Rest Rooms for Employees
Kitchens
Admission Room

Summary

- 1 The physical plant of a city cancer unit is outlined
- 2 The historical background is summarized
- 3 The system as to the procedure for the care of patients is given
- 4 The research problems to be met is touched upon

152 CLINTON ST

NOW THEY KNOW

An inquiring reporter seized his opportunity at the state convention in Rochester to find out "Why doctors write scientific titles and phrases in long word language which baffles many laymen." He buttonholed Dr. Peter Irving, whose job as Secretary and General Manager of the State Medical Society seemed to indicate him as the proper victim. The interview goes on:

"In titling scientific papers," Doctor Irving explained, "Latin in particular and often Greek are used to designate a particular type of disease condition."

"In the first place, it has always been necessary to use a word which means the same to people of all nations. The scientific term has a worldwide value in the medical profession."

"In the second place, the use of dead languages insures greater accuracy, because the words of Latin and Greek do not vary in meaning now. Modern language, being

living and on the move constantly, often varies in its word values."

"Prescriptions are written traditionally in Latin for the same reason—the phrases always mean the same thing. Therefore they are constantly accurate."

Doctor Irving thumbed the scientific program of the medical society. "Here is a paper," he said, reading, "Treatment of Polycythemia Vera."

"Polycythemia means 'too much hemoglobin—too many red cells in the blood.' Vera means 'true' as compared to 'false.'"

"Here's another—'Analgesia and Anesthesia in Obstetrics.' Analgesia means 'without pain,' anesthesia means 'without sensation.'"

Greek enters into other words commonly used by the layman, without, perhaps, his knowing what they really mean. There are, for instance, tonsillitis, appendicitis, laryngitis. "In each word, the Greek suffix 'itis' means 'inflammation.'"

GASTRIC ROENTGENOLOGIC CHANGES IN DEFICIENCY DISEASE

Response to Treatment

IAN G MACDONALD, M D, C M, *Cornwall*, ALFRED F HOCKER, M D, *New York City*, and R CAMERON MAY, M D, *Cornwall-on-Hudson*

A number of reported clinical studies have demonstrated the importance of the morphologic changes exhibited by the small intestine in certain dietary deficiency diseases. Mackie, Miller, and Rhoades,¹ by a special radiologic technic, were able to identify characteristic abnormal patterns of the intestine in seventeen cases of sprue. After a few days of adequate parenteral liver therapy these distorted outlines, coincident with clinical improvement² are replaced by essentially normal appearing radiographs. Similar changes in the outline of the small intestine have been noted in idiopathic steatorrhea,³ chronic ulcerative colitis,⁴ and experimental avitaminosis in animals.⁵

Of great importance is the recognition of dietary deficiency disease apart from the clinical entities such as sprue, pellagra, alcoholic polyneuritis, and steatorrhea. The essential history is that of a diet deficient in proteins and vitamins. The clinical picture is predominantly that of gastrointestinal dysfunction, often accompanied by peripheral nerve symptoms, progressive anemia, and some of the physical signs associated with the Addisonian type of anemia. Such cases usually show an achlorhydria.

The present report concerns a case of deficiency disease in which the radiographic appearance of the stomach seemed characteristic of a neoplastic growth of that organ. This patient has been followed for three years and the effect of dietary and liver therapy on the gastric pattern and capacity is presented.

Case History

S K., a fifty-three-year-old white female, first entered the Cornwall Hospital on May 7, 1934. She had been in good general health until December 1933, when she suddenly began to have daily emesis, non-projectile in type, and frequent attacks

of diarrhea. For several weeks she vomited most of the daily intake of food, and thereafter continued to have less frequent emesis but was able to retain small amounts of soft food. Her weight dropped from one hundred thirty-five to ninety-seven pounds. At times there was dull, non-radiating, epigastric pain, and much burning and eructation. In May 1934 the emesis again became persistent. She was only able to retain liquids.

The previous medical history was of little interest, except for chronic constipation of many years' standing. She had had five normal pregnancies, and an uneventful menopause at the age of forty-eight. For several years before admission she had existed on a diet largely deficient in meat, fresh fruits, and vegetables. Her preference was for a refined, denatured, soft carbohydrate menu.

Physical examination showed an undernourished, emaciated woman appearing chronically ill. There was a marked glossitis, but no atrophy of the tongue. Slight tenderness was present in the epigastrium. Blood examination showed 4.06 million red cells, seventy-one per cent hemoglobin, color index 0.9. The number and differential percentage of leukocytes was normal. The gastric content after alcohol test meal contained thirty-five per cent free HCL, sixty-seven per cent total acidity.

The appearance of the stomach by x-ray visualization is seen in Fig 1. The deformity of the pars pyloricus was constant, and approximately as depicted throughout fluoroscopy and on successive plates.

The patient was discharged for a trial of dietary management by her physician, but failed to cooperate and was not seen again until her readmission on July 28, 1935. In the interval she had existed on an exclusive diet of milk, egg albumin, and various fluids. The vomiting and dull epigastric pain had persisted. Her weight remained at ninety-seven pounds. In the several months preceding she had had increasing pains in legs and arms, numbness of the fingers, and visual disturbances. There was no complaint of stomatitis. Di-

From the Ogden Memorial Tumor Clinic, Cornwall Hospital

Fig 1

arrheal attacks were frequent. She claimed to have had emesis of blood and "pus" on one occasion, and occasional black stools.

On this examination there was atrophy of the lingual papillae, particularly along the lateral borders of the tongue, with persisting glossitis, no ulcers in oral cavity or pharynx. Upper abdomen was distended and flatulent. Tenderness in epigastrium was moderate. Muscular wasting was very evident. There was a pallor of skin and mucous membrane, with an icteric tinge. *Laboratory examination* red blood cells, 30 million, hemoglobin, seventy per cent, color index, 11, smear showed red blood cells tending to be macrocytic, normal differential leukocytes percentage, with a total of 6,000 per cu mm. Gastric analysis revealed an absence of free hydrochloric acid on fractional alcohol test meal. Total acidity averaged ninety per cent. None of five specimens removed contained blood or mucus, and all contained lactic acid.

The radiographic appearance of the stomach is seen in Fig 2. The stomach again showed a constant deformity throughout a prolonged fluoroscopic examination and in interval plates. The report on these pictures was (Dr R W Thompson) "Stomach, No six hour residue. Hook shape. Slightly ptosed—tender over pars media. Rugae very coarse and stringy but parallel. Constant filling defect at outer border of pars media. Motility rapid." Also noted were changes in the small intestine—variation in caliber, segmentation, pocketing.

The history was not consistent with gastric carcinoma. It was recognized that this

patient was a problem in dietary deficiency and that the whole clinical picture might be due to a deficiency disease. A benign tumor of the stomach wall was considered as a possible cause of the radiographic appearance, and in view of the achlorhydria it was decided to explore the abdomen to rule out the possibility of gastric neoplasm.

At operation the stomach was moderately ptosed, but entirely without gross changes. Throughout the wall was thin and pliable. The stomach was not opened, but there was no evidence of thickening in the area in which the filling defect was visualized. Other exploration of the abdomen was without abnormal findings.

Shortly after operation intramuscular injections of liver extract were commenced, giving two cc (equivalent to ten gms of fresh liver) two or three times a week. After discharge, these injections were continued, dilute hydrochloric acid given by mouth, and an adequate dietary regime enforced. Clinical improvement was rapid under these measures, and within two months she had gained twenty lbs. Omission of the liver extract for several weeks resulted in a mild return of symptoms, which disappeared after further liver therapy. She has remained clinically well, with a weight of 120-125 lbs. On May 15, 1936, a re-examination by x-ray showed an outline as seen in Fig 3. The capacity of the stomach is greatly increased (one-third or more), the outline is regular and the borders smooth. Fluoroscopic examination showed normal motor activity. She has remained well with the administration of several doses of liver extract monthly.

Fig 2

Comment

Characteristic changes in small intestine pattern on roentgen visualization were remarkably constant in the seventeen cases of sprue reported by Mackie, Miller, and Rhoades¹. There was striking variations in the contour and caliber of the intestinal lumen. Peristalsis was very irregular with segmental pocketing of the barium which sometimes resembled diverticulae. The mucosa gave evidence of thickening, and the lower ileum appeared to have areas of thickening of the entire wall. There was a prompt disappearance of these changes after specific therapy by liver extract parenterally injected. The oral administration of liver was without value, suggesting a loss of absorptive power in the intestinal mucosa. Fairley⁷ has shown that the derangement of the ileum in this disease is responsible for defective absorption of fat, vitamin D, and calcium.

Experimental avitaminosis in animals results in certain abnormalities of the intestinal tract. Plummer found on withdrawal of vitamin B from the diet that the tonicity of the intestinal musculature became less, as did the amplitude, rate and length of time during which spontaneous contractions occur in the isolated segment.

Whatever part mucosal changes may play in the production of these abnormal intestinal patterns in sprue, it is certain that there is also a marked alteration in the rhythmic contracture of the musculature. This appears to be the essential factor in the reproduction of the same picture in cases of ulcerative colitis and in experimental avitaminosis. The prompt change towards a normal pattern with liver therapy suggests that such intestinal derangement is due to lack of an essential food factor. Miller and Rhoades have advanced the theory that the anti-pernicious anemia substance may be that factor, and that the conditioning of the functional activity of the small intestine may depend upon that substance.

A study of the case here reported seems to indicate that the motor activity of the gastric musculature may be equally affected in various states of dietary deficiency disease. The history is of a particular interest in view of the gradual development of deficiency disease under

observation. This patient had existed on a deficient diet for some years before the first admission in 1934, and her gastrointestinal symptoms were undoubtedly due to a deficiency disease. At that time, however, she had not developed anemia and there was a relatively normal amount of free hydrochloric acid on gastric analysis, although attacks of diarrhea were frequent.

During the thirteen months that elapsed until the second admission, there was an

Fig 3

extraordinary restriction of diet, with the development of a clear-cut deficiency state, manifested by neuritis, numbness of the fingers, visual failure, achlorhydria, and mild anemia of macrocytic, hyperchromic type⁸. On each admission the gastric radiographs presented a constant filling defect on the greater curvature of the stomach. Although the change in x-ray localization and the clinical history did not seem compatible with a gastric carcinoma, on each occasion the appearance was consistent with an intrinsic neoplasm of the stomach. The response to liver and dietary therapy over a period of nine months was as striking clinically as in the disappearance of the abnormal radiographic findings. The stomach not only presents an even contour with smooth borders, but its capacity has greatly increased.

These abnormal x-ray findings are even

more remarkable than those observed in the small intestine, in that the gastric pattern has taken the form of a constant filling defect or deformity which remains localized in one area of the gastric wall over the two to three hour period required for combined fluoroscopic examination and interval taking of films. The operative findings failed to reveal any evidence of mucosal or other hypertrophy in the stomach wall, and in Fig 2 it may be noted that the rugae present a roughly paralleled outline. Hence it must be assumed that the departure from normal form must be due to deranged motor activity. It has been established by Cannon's experiments that the stimulus to motor activity in the body of the stomach is myogenic, i.e., directly originated in and determined by the muscle fibers themselves. Possibly the conditioning of the functional activity of the gastric musculature may also depend on some factor lacking in these cases, which is supplied by liver extract as in an adequate diet.

Snell has stated that the abnormal intestinal patterns in deficiency disease can be entirely accounted for by deficient absorption from the small-intestinal mucosa. This explanation does not apply to similar changes in the stomach. May not the mucosal changes described in the small intestine be secondary to alternating stasis and contraction resulting from motor derangement? It is interesting to note that the radiographs here reported also showed an abnormal intestinal pattern characteristic of deficiency states, which after treatment largely disappeared.

Such radiographic changes as reported here probably will not be frequent. They do, however, illustrate the essential importance of ascertaining the dietary background of such ill-defined gastrointestinal syndromes accompanied by hyperchromic type of anemia. Where a history of dietary deficiency can be established with such suggestive findings as atrophic glossitis, intraoral ulcers, nervous manifestations, or peripheral edema, a therapeutic

trial by parenteral injections of liver and an adequate diet is indicated. The presence of an abnormal gastric pattern as seen in these cases, is not definitely proof of carcinoma. In such cases, providing the patient can be kept under accurate observation and surgical exploration done if he does not show prompt improvement, liver and dietary therapy should be tried for a brief period. In cases of deficiency disease, clinical improvement should be accompanied by a return of the gastric outline towards a normal pattern.

Summary

A case of dietary deficiency disease is reported in which gastric radiographs showed a constant filling defect and irregular outline suggestive of a neoplastic growth in whom surgical exploration revealed a stomach without evidence of gross pathology. A return to normal x-ray appearance and with increased capacity occurred concomitantly with clinical cure under parenteral liver therapy and adequate diet. The patient exhibited the small-intestinal deformities that have been observed in sprue.¹ It is suggested that such alterations in the stomach, and possibly in the intestine, are dependent primarily upon derangement in myogenic motor function, which in turn results from the deficiency of some factor which conditions the functional activity of the stomach and small intestine. This factor seems to be supplied by the parental injection of liver extract and adequate diet.

TREATMENT OF THE COLLES' FRACTURES

PORTEOUS E JOHNSON, MD, *New York City*

Among the unprecedented advances in traumatology during recent years, there has been very little interest shown in Colles' fractures. Our chief surgeons have been too busy with their gadgets for curing fractured neck of femur or doing arthroplasties to bother with this very common and most instructive lesion, and consequently have relegated its care to the intern or resident. Thus it has been my privilege to observe the wide differences of opinion as to how these cases should be treated and to have taken part in the treatment of several hundred of them.

The fact that all methods of treatment which follow the fundamental outline of reduction, immobilization, and physiotherapy, yield some excellent results, is due to the fact that there is considerable difference between the pathology of different Colles' fractures.

The term Colles' fracture, as used today refers to any compression or extension fracture of the lower end of the radius. The details of the pathology vary with the patient's individual bone structure, as determined by his age, sex, occupation, etc., with the amount, direction, and duration of the fracturing force, and with the state of muscle tone and the position of the wrist at the time of fracture.

This statement implies a rather wide variety of lesions when the details of the pathology are considered, and experience shows this to be true.

The shortening which occurs in Colles fractures differs from the shortening in shaft fractures in that it is not due to overlapping of the fragments, but to a crumbling, or "microscopic comminution" of the bone along the fracture line. The angulation is dependent more upon the varying amounts of comminution in different locations than upon malposition of the fragments. Thus if one-quarter inch of bone is fragmented by comminution of the ventral surface, while three-quarters inch is destroyed on the dorsum, there will be about one-half inch

shortening and a dorsal tilt of the distal fragment of several degrees, without overlapping and with considerable stability in the new position.

The small intervening comminuted fragments are often not demonstrable by x-ray and may be reabsorbed or take part in the callus formation of the healing process. Their presence probably accounts in part, for the rapid firm union which generally follows fractures through cancellous bone.

Such fractures are generally more stable and would heal more rapidly in this original position than in any other which could be obtained by attempts at reduction. Some surgeons, realizing this fact, make no attempt to improve the position unless the amount of angular deformity precludes the possibility of a fair functional result. They simply stabilize the fracture as it is, with a leather or adhesive wrist band, and immediately start physiotherapy. Many of these ugly looking wrists show surprisingly good functional results to justify the procedure.

At this point let me recall to you the fact that other things being equal, the amount of functional disability resulting from a Colles' fracture is directly proportional to the amount of the uncorrected angular deformity, so that a study of the angular displacement in the lateral x-ray view is the most important evidence as to whether or not reduction is necessary or satisfactory after it has been done.

Particularly in elderly people it is often unwise to disturb the fracture if this angular deformity is not marked. This also applies to younger persons showing an arthritic tendency.

Others lay more stress on anatomical restoration. By traction and manipulation, they perch the distal fragment precariously with its anteromedial corner resting on the most distal projection of the proximal fragment and suspend it there until the surrounding areas have filled in with bone. They suspend it

Read before the Clinical Society of Morrisania City Hospital, January 27, 1937

there by ligaments and tendons made tense by immobilization in an extreme position of flexion, pronation, and ulnar deviation at the wrist. It frequently takes six weeks, or more, for the areas of "microscopic comminution" to become filled with firm callus, but they are rewarded by a beautiful restoration of normal contour, although the hand and fingers are a bit stiff and useless.

Obviously the best judgment calls for some intermediate course in most cases. Many surgeons have adopted a more or less routine middle course which they use regardless of the individual peculiarities of the case under consideration. Perhaps the most popular is a manipulative reduction followed by a period of immobilization in the Cotton-Loder position. They change this after a prescribed length of time of four to twenty-one days to a neutral position, and some use a third period of immobilization in the cock-up position. It is generally agreed that the fingers should be actively exercised from the first.

The Cotton-Loder position is unquestionably a very disabling form of treatment and, even in a normal wrist, will cause pain and swelling, and prevents a wide range of finger motion. For that reason we reserve that form of treatment for what we find to be rare—those cases which cannot be adequately treated otherwise.

We also cannot believe that any case actually requiring the Cotton-Loder position for maintenance at the time of reduction, will have increased in stability sufficiently in four to seven days to permit a change to the neutral position at that time without displacement. Such an early improvement in stability is contrary both to experience and to our knowledge of the physiology of repair. Consequently, when a position of extreme flexion and ulnar deviation is found necessary to maintain a satisfactory reduction, we continue its use for ten to fourteen days.

The ability to determine the maximum amount of extension which is compatible with the maintenance of a satisfactory reduction depends upon two simple clinical signs which can be elicited at the time of reduction.

The first of these is a clinical test for reduction. Except in the very obese pa-

tient, the fracture line and the posterior surfaces of the two fragments can be easily palpated under anesthesia after pressing away the edema and hematoma. Before reduction there is a distinct ledge palpable, formed by the distal fragment overhanging the proximal, and there is felt to be a distinct angulation between the posterior surfaces of the two fragments which is proportional to the amount of posterior tilt of the distal fragment.

By direct traction on the distal fragment, followed by firm pressure exerted anteriorly while traction is still maintained, the displacement is corrected. This is proven clinically by a disappearance of the ledge and a realignment of the two fragments, as determined by palpation of the posterior surface of the radius. Occasionally, if there has been too much "microscopic comminution," the ledge cannot be completely obliterated, but the alignment must be corrected in order to restore the normal orientation of the distal articular surface of the radius.

At the end of the manipulation, the hand is in the Cotton-Loder position. Now, without external support, but with gentle palpation of the posterior surface of the radius to determine any change in the contour of the bone, the wrist is slowly extended. If a moderate cock-up position can be obtained without any change in the position of the fragments, the extremity is immediately immobilized in that position. Generally, however, at some point in the process of extension there is felt (and seen) a sudden backward shifting and tilting of the distal fragment, frequently with the production of audible crepitus. The degree of extension at which this occurs is carefully noted and, after correcting the reduction, the extremity is immobilized in slightly less extension than the point at which the reduction slipped on the first trial. Occasionally the fragments are felt to slip almost immediately after the extreme flexion is released, and in these, the position of the distal fragment should be shifted slightly in an attempt to find a more stable position for it against the end of the proximal fragment. Frequently a fragment which is very unstable after the first reduction, can be made to hold a satisfactory position by applying some

impacting force and moving the fragments slightly from side to side while maintaining the corrected position and alignment by a good grip on the two fragments

If a position of stability cannot be found, the extremity is regrettably immobilized in the Cotton-Loder position and kept there for ten to fourteen days, the time depending mainly upon the findings at the time of reduction

It is obvious that with such a plan of treatment there is great danger of losing the reduction during the application of splints or under loose or poorly fitting splints. This is prevented by the use of anterior and posterior molded plaster splints applied in the following manner

The splints are not made until we are ready for them and are made from rather slow-setting plaster. They are immediately applied to the forearm and hand with the wrist in ten to fifteen degrees more flexion than the predetermined optimum. They are immediately secured in position by one or two layers of gauze bandage carefully applied. We then support the fragments by pressure exerted over the dorsum of the distal fragment by the thumb, while the fingers of the same hand are held flat against the ventral surface of the proximal fragment. We then carefully extend the wrist to the desired amount with our other hand and hold this position and pressure steadily until the plaster is hard. The splinted forearm and hand are then securely wrapped with gauze bandage and adhesive, and the slight depressions caused by the pressure of thumb and fingers continue to exert pressure where it is most needed throughout the period of immobilization.

Any fracture which is immobilized with the wrist in any degree of flexion is changed after ten days to two weeks. New splints are applied with the wrist in as much extension as can be obtained without causing pain. If possible, daily physiotherapy is started at this time, consisting of active motion, whirlpool baths, radiant heat, and massage.

Immobilization is continued until the point tenderness at the fracture line has disappeared, usually from three to five weeks.

No passive motion of any sort is per-

missible until after this local tenderness has disappeared. This sign has been found much more reliable than the time interval or the x-ray findings in determining the completion of firm union, both here and elsewhere.

Before closing let me say a few words about anesthesia. General anesthesia has certain obvious disadvantages. Local anesthesia consisting of the injection of novocain directly into the fracture line, has lately been very popular. However, it has three definite disadvantages. The introduction of the needle into the fracture site is very painful. The distention caused by the injection of the novocain is very painful. And there is the very real danger of introducing infection by thus changing a simple fracture into a compound fracture. We feel that a nerve block anesthesia of the radial, medium, and ulnar nerves in the region of the elbow is a much safer and more painless procedure, and it does not obscure the physical signs and increase the difficulty of reduction by further distending an already swollen area.

Summary

1 Every Colles' fracture should be considered an individual problem, and not treated by any routine procedure.

2 The treatment which will produce the best anatomical result will often not produce the best functional result, and careful judgment is necessary to assay the relative values of conflicting indications.

3 X-ray and physical examination are not enough to determine the significant details of the pathology, but certain signs which may be elicited during manipulation under anesthesia are the most important indications as to the best type of treatment.

4 Care in the application of molded plaster splints is of utmost importance in maintaining reduction in a position compatible with a good functional result.

5 Disappearance of local point tenderness over the fracture line is the most reliable safe test for solid union.

6 Nerve block anesthesia is the best form of anesthesia for the reduction of Colles' fractures.

there by ligaments and tendons made tense by immobilization in an extreme position of flexion, pronation, and ulnar deviation at the wrist. It frequently takes six weeks, or more, for the areas of "microscopic comminution" to become filled with firm callus, but they are rewarded by a beautiful restoration of normal contour, although the hand and fingers are a bit stiff and useless.

Obviously the best judgment calls for some intermediate course in most cases. Many surgeons have adopted a more or less routine middle course which they use regardless of the individual peculiarities of the case under consideration. They change this after a prescribed length of time of four to twenty-one days to a neutral position, and some use a third period of immobilization in the cock-up position. It is generally agreed that the fingers should be actively exercised from the first.

The Cotton-Loder position is unquestionably a very disabling form of treatment and, even in a normal wrist, will cause pain and swelling, and prevents a wide range of finger motion. For that reason we reserve that form of treatment for what we find to be rare—those cases which cannot be adequately treated otherwise.

We also cannot believe that any case actually requiring the Cotton-Loder position for maintenance at the time of reduction, will have increased in stability sufficiently in four to seven days to permit a change to the neutral position at that time without displacement. Such an early improvement in stability is contrary both to experience and to our knowledge of the physiology of repair. Consequently, when a position of extreme flexion and ulnar deviation is found necessary to maintain a satisfactory reduction, we continue its use for ten to fourteen days.

The ability to determine the maximum amount of extension which is compatible with the maintenance of a satisfactory reduction depends upon two simple clinical signs which can be elicited at the time of reduction.

The first of these is a clinical test for reduction. Except in the very obese pa-

tient, the fracture line and the posterior surfaces of the two fragments can be easily palpated under anesthesia after pressing away the edema and hematoma. Before reduction there is a distinct ledge palpable, formed by the distal fragment overhanging the proximal, and there is felt to be a distinct angulation between the posterior surfaces of the two fragments which is proportional to the amount of posterior tilt of the distal fragment.

By direct traction on the distal fragment, followed by firm pressure exerted anteriorly while traction is still maintained, the displacement is corrected. This is proven clinically by a disappearance of the ledge and a realignment of the two fragments, as determined by palpation of the posterior surface of the radius. Occasionally, if there has been too much "microscopic comminution," the ledge cannot be completely obliterated, but the alignment must be corrected in order to restore the normal orientation of the distal articular surface of the radius.

At the end of the manipulation, the hand is in the Cotton-Loder position. Now, without external support, but with gentle palpation of the posterior surface of the radius to determine any change in the contour of the bone, the wrist is slowly extended. If a moderate cock-up position can be obtained without any change in the position of the fragments, the extremity is immediately immobilized in that position. Generally, however, at some point in the process of extension there is felt (and seen) a sudden backward shifting and tilting of the distal fragment, frequently with the production of audible crepitus. The degree of extension at which this occurs is carefully noted and, after correcting the reduction, the extremity is immobilized in slightly less extension than the point at which the reduction slipped on the first trial. Occasionally the fragments are felt to slip almost immediately after the extreme flexion is released, and in these, the position of the distal fragment should be shifted slightly in an attempt to find a more stable position for it against the end of the proximal fragment. Frequently a fragment which is very unstable after the first reduction, can be made to hold a satisfactory position by applying some

impacting force and moving the fragments slightly from side to side while maintaining the corrected position and alignment by a good grip on the two fragments

If a position of stability cannot be found, the extremity is regretfully immobilized in the Cotton-Loder position and kept there for ten to fourteen days, the time depending mainly upon the findings at the time of reduction

It is obvious that with such a plan of treatment there is great danger of losing the reduction during the application of splints or under loose or poorly fitting splints. This is prevented by the use of anterior and posterior molded plaster splints applied in the following manner

The splints are not made until we are ready for them and are made from rather slow-setting plaster. They are immediately applied to the forearm and hand with the wrist in ten to fifteen degrees more flexion than the predetermined optimum. They are immediately secured in position by one or two layers of gauze bandage carefully applied. We then support the fragments by pressure exerted over the dorsum of the distal fragment by the thumb, while the fingers of the same hand are held flat against the ventral surface of the proximal fragment. We then carefully extend the wrist to the desired amount with our other hand and hold this position and pressure steadily until the plaster is hard. The splinted forearm and hand are then securely wrapped with gauze bandage and adhesive, and the slight depressions caused by the pressure of thumb and fingers continue to exert pressure where it is most needed throughout the period of immobilization.

Any fracture which is immobilized with the wrist in any degree of flexion is changed after ten days to two weeks. New splints are applied with the wrist in as much extension as can be obtained without causing pain. If possible, daily physiotherapy is started at this time, consisting of active motion, whirlpool baths, radiant heat, and massage.

Immobilization is continued until the point tenderness at the fracture line has disappeared, usually from three to five weeks.

No passive motion of any sort is per-

missible until after this local tenderness has disappeared. This sign has been found much more reliable than the time interval or the x-ray findings in determining the completion of firm union, both here and elsewhere.

Before closing let me say a few words about anesthesia. General anesthesia has certain obvious disadvantages. Local anesthesia consisting of the injection of novocain directly into the fracture line, has lately been very popular. However, it has three definite disadvantages. The introduction of the needle into the fracture site is very painful. The distention caused by the injection of the novocain is very painful. And there is the very real danger of introducing infection by thus changing a simple fracture into a compound fracture. We feel that a nerve block anesthesia of the radial, median, and ulnar nerves in the region of the elbow is a much safer and more painless procedure, and it does not obscure the physical signs and increase the difficulty of reduction by further distending an already swollen area.

Summary

1 Every Colles' fracture should be considered an individual problem, and not treated by any routine procedure.

2 The treatment which will produce the best anatomical result will often not produce the best functional result, and careful judgment is necessary to assay the relative values of conflicting indications.

3 X-ray and physical examination are not enough to determine the significant details of the pathology, but certain signs which may be elicited during manipulation under anesthesia are the most important indications as to the best type of treatment.

4 Care in the application of molded plaster splints is of utmost importance in maintaining reduction in a position compatible with a good functional result.

5 Disappearance of local point tenderness over the fracture line is the most reliable safe test for solid union.

6 Nerve block anesthesia is the best form of anesthesia for the reduction of Colles' fractures.

IMPORTANCE OF A ROUTINE WASSERMANN TEST IN PRIVATE PRACTICE

Case Reports

MARIE PICHEL WARNER, B S, M D and BENJAMIN W WARNER, M D,
Bronx

It is the custom in our office to take blood for routine Wassermann tests on all new patients presenting themselves for examination for relief of symptoms, for a general physical examination, for a premarital examination, and on all prenatal patients, in fact, all patients excepting emergencies and those who come for special advice, such as contraception *per se*. The specimens of blood are sent to the Department of Laboratories, Department of Health of the City of New York, where serologic tests (Wassermann tests) are performed free of charge.

We are convinced of the wisdom and necessity of routine Wassermann tests for syphilis in private practice. We emphasize this fact because in the present drive to eradicate syphilis, there is a controversial issue as to whether the private practitioner is qualified or willing to actively participate in diagnosing and treating syphilis, or whether the problem can be better handled through the medium of clinics. The private practitioner, with the cooperation of the local Departments of Health, can and should be of invaluable aid in this newest public health drive.

In our last five hundred and twenty-eight private patients in our office on whom Wassermann tests were performed, seven were found to have syphilis, which was unknown to them. In our small series there is an incidence of 1.32%, representing patients with latent, undiagnosed syphilis. We have excluded those patients with positive serology who knew or suspected that they had syphilis. Our patients represent a cross-section of the middle class social and economic group which constitutes the bulk of all private practice. The status ranged from domestics to successful professional and business men and women.

The patients with positive serology, with the exception of one case of congenital lues, had complained of vague symptoms for many years and had consulted many physicians without a diagnosis of their condition being made or relief given. Excluding the case of congenital syphilis with definite stigmata, there was only one other case with clinical evidence of syphilis, i.e. Argyll Robertson pupils. Thus, in five patients syphilis was discovered because of the routine habit of doing a Wassermann test and not relying on clinical indications or a history of luetic infection. A recent experience prompted a review of our records and this report.

A five weeks old baby was brought to the office for feeding advice. The baby was marasmic and presented clinical symptoms and signs of congenital syphilis. There was difficulty in obtaining blood from the baby and a Wassermann was done on the mother's blood. The result was a four plus positive reaction. The mother had been a private patient of another physician and had been delivered in a private hospital but had never been given a prenatal Wassermann test. She had been delivered six years previously of another child who was living, and had not had a prenatal Wassermann test done during that pregnancy. A Wassermann test performed on this six year old boy resulted in a three plus reaction. This woman had had another hospital admission as a private patient for a laparotomy three years previously and a Wassermann had not been performed. The father had a negative blood Wassermann, but is being studied further. The family belongs to that economic-social stratum or middle class group that represents the substance of private practice.

This case constitutes a direct challenge to private practitioners to perform routine serologic tests on every pregnant woman. The time will come shortly

Read before the North Bronx Medical Society, January 7, 1937

when congenital syphilis will be an extremely rare occurrence. In fact, it will be as rare as ophthalmia neonatorum if physicians perform routine Wassermann tests as zealously as they practice prophylaxis for the eyes, without regard for the social or economic status of the patient. The concept that syphilis exists only in the clinic type patient is a dangerous one and lulls the physician into a false sense of security. In the words of Stokes, "The physician's index of suspicion is lowered." Women would accept a routine Wassermann prenatally in order to have a healthy child, just as they accept all the inconveniences and discomforts of their pregnancy.

A questionnaire sent by the American Social Hygiene Association¹ to two hundred and fifty prenatal clinics reported that ninety-three per cent of the clinics perform a routine Wassermann test. The others use the test when indications exist. This latter method overlooks many cases. A questionnaire was likewise sent to two hundred and fifty physicians, all members of one or another association of obstetricians. Of the eighty-two who responded, forty-two stated that they make blood tests on all pregnant patients. Forty said that they do not. The percentages of positives ranged from 0 to 35 per cent. Those physicians who have found no positive reactions are just as emphatic as to the importance of routine testing as are those who report a higher percentage.

There is nothing novel to report about the variability and multitude of symptoms that syphilis can cause, the number of diseases it may simulate, or its latency or asymptomatic nature. Need we repeat the words of Osler that were impressed upon us so indelibly in our student days and are now forming the theme for lay publicity—that "Syphilis is the great imitator?" It is also repetitious to cite the following cases that surely must occur in every physician's practice, yet Wassermann tests are not performed.

A white woman, fifty-five years of age, married, had thirteen living children. She came from a neighboring state and was visiting her son in New York. She complained of pain and stiffness in her knees.

Examination revealed obesity, lowered metabolism, and large varicosities of both lower extremities. There were no neurologic signs or symptoms and it seemed apparent that the pain in her knees was due to either her lowered metabolism or her varicosities. A routine Wassermann test gave a four plus result. Under proper therapy the pains in her knees disappeared. The source of infection as in the other case was unknown. The husband and all the children had negative serology.

A white man, aged forty, married, presented symptoms and signs referable to the central nervous and cardiovascular systems. He had mental changes, Argyll Robertson pupils, and a dilated, tortuous aorta. Wassermann reaction was four plus. One of us (BWV) had been present at this man's wedding sixteen years previously and knew his bride ever since childhood. Fortunately, the wife was not infected, but the husband's mental and physical deterioration disrupted the marriage. A premarital physical examination would have prevented this medical and social catastrophe.

Extensive education of both the physicians and the public is necessary before this newer phase of preventive medicine, namely, a premarital physical examination, becomes an established procedure. Passage of laws compelling premarital Wassermann tests without the intelligent cooperation of the public may fail. e.g., Connecticut passed a law with such a requirement, but we understand that the couples cross the state line to New York for their marriage ceremony. If the physicians use smaller caliber, sharp intravenous needles so that there will be no pain or psychic trauma associated with a venepuncture and the drawing of five c.c. of blood, and if more educational work were done, the public would cooperate more willingly. It is pleasing to note that in our premarital physical examinations we have not found, to date, any positive serology. Unfortunately, not all prospective grooms present themselves for examination, nor is a Wassermann done routinely on prospective brides. Many expectant brides consult one of us (MPW) at the last moment, a day or even a few hours before the wedding, and in such instances we do not do a blood Wassermann unless requested. The ideal state will be attained when the

prospective bride and groom present themselves in ample time before marriage to a physician or to their respective physicians interested in this newer phase of medicine, for a physical examination including a blood Wassermann and such special examination and advice as may be necessary or sought as preparation for marriage

Two cases were diagnosed in domestic help. In one patient the disease was symptomless and in the other there were generalized arthritic pains, vaginal discharge, and a history of an illegitimate stillbirth. The question of routine Wassermann tests on all domestic help is very important, irrespective of the individuals' race or color. Both of these patients were negro women and had mixed infections of gonorrhea and syphilis.

Two other cases were obese white women in their late forties who had vasomotor and nervous symptoms referable to the menopause and without any clinical indications of syphilis. These women complained of headaches, fatigue, hot flushes, and requested dietary advice in order to reduce. There were no clinical indications of syphilis but a routine test gave positive results. Under therapy many of the symptoms, especially the headaches, disappeared.

Conclusion

There is an active, concerted attempt on the part of health authorities to eradicate syphilis. The health authorities are stressing the need and importance of clinic and hospital facilities for the task. Only recently are hospitals recognizing the importance of routine serological tests in all of their outpatient and inpatient

departments. It is believed that only by diagnosing the individual case will syphilis be controlled and the incidence materially reduced.

Many of the authorities are unpromising and impatient in their criticism of the role of the private practitioner. Much of this criticism is deserving. The physician must become more syphilis conscious, his "index of suspicion" must be raised, and the Wassermann test must occupy the same place in a routine medical examination as taking temperature or a urine analysis.

Let us not, as private practitioners, wait until we are regimented into the plan for syphilis control, but rather let us voluntarily enlist and expand our services. In recognizing and healing syphilis we are diagnosing and curing the patient and acting further as individual health officers in the broader scheme of public health. We are consulted in confidence and privacy by the distracted and unfortunate patient who is afflicted with venereal disease. With cooperation of the public health facilities we can render efficient, satisfactory service.

Acknowledgment

We are grateful to Mr. John Koopman of the New York City Department of Health for his cooperation and assistance in compiling our records of Wassermann tests.

THERE ARE SPIRITUALIST QUACKS, TOO

False spiritualistic mediums and quacks were attacked at a spiritualist convention in Rochester in the week previous to the meeting of the State Medical Association. Such unscrupulous spiritualistic practitioners are outside the pale of organized spiritualism, they are irregular, and are likely to give deleterious advice, it seems. The public should stick to the old-line, regular, authorized, orthodox mediums. Fortune tellers who use their office for profit were con-

demned as unethical. Nor was that all denounced along with the quacks and fortune tellers were the M.D.'s. The Rev. E. Ann Taylor, of Brooklyn warned mediums to avoid medical diagnosis and declared the State Medical Society is ready to "bear down on all who make use of spiritual gifts to tell people of their personal ills." It is hoped that even after this alarming information the State Medical Society will bear up.

CARCINOID OF APPENDIX

Ruptured Ovarian Cyst

JULIUS LEBOVITZ, M D, *Woodside*

The carcinoid tumors have long fascinated the clinical and pathological investigators, because of the peculiar characteristics of these tumors. We have the atypical cell proliferation and infiltration so characteristic of carcinoma, yet lacking the malignant features, such as metastasis and recurrences. Even the cellular proliferation and infiltration do not bear the mark of the highly destructive type but merely additional cell deposits to the original tissue structure or substitution of the maternal tissue grounds, secondly, there is a definite tissue limitation of their proliferative and infiltrative tendencies, such as endothelial cell layers. In other words, we are dealing here with tumors whose morphological appearances are that of a carcinoma yet lacking some of the biological characteristics and behavior of the carcinomatous cell.

The difference probably lies in some factor or factors (endocrine and others) which will bring about some cytoplasmic changes in the cell in an organ where normally and ordinarily, according to their physiological functions, cellular destruction, reproduction, and replacement are taking place. But, according to these cytoplasmic changes which are not known to us, in one case we find a cell of lesser malignant characteristics and in another, highly malignant features determining the benignity or malignancy of the tumor. The carcinoid tumors in the majority of cases are of the benign type. Merlin describes the condition for the first time in 1838. Rokitsansky in 1867 described four cases, calling them colloid carcinomas. Miller gave it the name carcinoid or pseudocarcinoma analogous to the Oberdorfer's carcinoid occurring in the small intestines. Moskowitz¹ reviewing the literature, collected eighteen cases including his own. Jackson² in 1923 collected three hundred seventeen cases in the literature. Its frequency is

known to be about one-third to one-half of one per cent of the appendices examined. McCarthy reporting 8,039 appendectomies from the Mayo Clinic found forty cases of carcinoid of appendix which is approximately one-half of one per cent. The majority of cases reported appeared between the third and fourth decade, more frequently in female than in male, probably due to the greater proportions of appendectomies performed in the course of gynecological operations. Grossly these tumors appear as localized tumescences, particularly on the tip or diffusely involving the entire appendix, obliterating the lumen. They may be of the scirrhus type or colloid type or mixed. At times the involvement is so small that it may be entirely overlooked. The tumors appear yellowish in color. Histologically you find epithelial cells grouped in the submucosa extending into the muscularis, very rarely in the subserosa or in the serosa. The most complete analysis came from Masson³ in 1928 who examined fifty cases. According to Masson, the carcinoid cells result from the proliferation of the epithelium of the Lieberkuehn crypts, the so-called argentaffin cells. According to him the carcinoids are tumors of the chromaffin system. The name argentaffin comes from the ability of the granules of the cells to reduce ammoniacal solution of silver.

Case Report

H M, twenty-four years old, married, was admitted to the Boulevard Hospital November 8, 1936. Patient had the usual childhood diseases, no other important illnesses. Menstruation started at the age of twelve, twenty-eight days type, lasting four or five days. Last menses started four days prior and still menstruating at the time of admittance to hospital. For two years she complained of pains in the right side, independent of menstrual periods. A G I series

Read before the Boulevard Hospital Clinical Society, January 27 1937

taken at the Telephone Company proved to be negative except, as the report stated, a delayed emptying of the appendix. On the day of admission, about 11 A.M. patient was suddenly seized with pain, cramplike in character, in the R.L.Q. which increased in intensity, she had vomited several times. On physical examination at 5 P.M. an acutely ill patient was found with definite rigidity in R.L.Q. and rebound tenderness. Bimanual examination was rather unsatisfactory because of hypersensitivity of patient, yet some resistance was felt on the right side of uterus. Temperature 99.8, pulse eighty-eight, blood pressure 120/74. I advised hospitalization. Patient was admitted to hospital 5:20 P.M. with diagnosis of acute appendicitis, and possible ruptured right ovarian cyst. RBC 3,800,000, WBC 12,800, eighty per cent poly, urine 2+ acetone. Due to the patient's condition, laparotomy was decided upon.

Under gas oxygen anesthesia a midline incision was made, the peritoneum appeared bluish in color, indicating free peritoneal bleeding. Peritoneum was opened, the cavity containing a good deal of free blood and also numerous blood clots, which were removed. Uterus was found normal in size and position, left adnexa normal, right tube normal, right ovary showed a small apple-sized corpus luteum cyst. The upper surface of the cyst showed a half a dollar rent from which active bleeding came. The right ovary was removed, and the pedicle ligated. I proceeded to explore the appendix, which was found in a retrocecal position and completely retroperitoneal. The parietal peritoneum on the lateral aspect of cecum incised and appendix removed, parietal peritoneum resutured, abdomen closed in layers. Patient made an uneventful recovery, left the hospital in nine days, and at present is fully recovered and returned to her work.

Pathological Report (Dr Carl Boettiger)

Nature of specimen Appendix and left ovary. Appendix fifty by ten mm. The distal twenty mm is covered over with a dense fibrous membrane. On section the lumen is completely closed. The mucosa cannot be differentiated. Ovary seventy by thirty-five by thirty mm. One section consists of rim of ovarian tissue ten mm. in thickness surrounding a cavity with contents evacuated. The lining membrane is smooth.

Pathological Report Section of appendix, the mucosa is tremendously hyperplastic showing irregularly shaped acini and chords of cells filling up the entire lumen. The lymphoid structures are absent. In the muscularis and serosa are irregularly shaped chords of cells. Ovary shows a number of small retention cysts. One large cyst cavity lined by several layers of luteal cells.

Diagnosis Luteal cyst of ovary. Probable carcinoma of appendix.

P. S. This type of tumor is usually of low malignancy and does not spread or metastasize. Its removal will probably be all that is required.

Summary

1 A case of carcinoïd of appendix is presented which was removed in the course of a laparotomy for a ruptured luteum cyst.

2 The carcinoïd invades the subserosa and partially the serosa which is a rare occurrence.

4920-43RD AVE.

INJUSTICE TO A CHIROPRACTOR

A California chiropractor recently complained to *California and Western Medicine* because it had listed him as "guilty of burglary, probation three years." "The notation is incorrect," he wrote indignantly, "I was charged with receiving stolen goods—not burglary." The editor thereupon looked into the matter and found this police report:

Upon information that the Los Angeles Wholesale Drug Company was losing merchandise over the weekend, we staked out on the place and observed Clark the "Doctor of

Chiropractic" and Codefendant Beswick drive up in an Essex sedan, belonging to Codefendant Beswick, observed defendant enter this store and remove seventeen cases of assorted drugs. Apprehended Beswick at Twelfth and San Pedro, and we came back with him and found this defendant Clark hiding behind packing cases upstairs.

"In accordance with the doctor's request, we are glad to state that he was only found guilty of receiving stolen goods and not of burglary," says the California editor.

SEQUENCE OF INFECTIOUS DISEASES IN THE UPPER AND LOWER RESPIRATORY TRACT

Anatomical and Clinical Considerations

NATHAN SETTEL, M D, F A C S, *New York City*

Adjunct Professor in Rhinology, New York Polytechnic Medical School and Hospital

In our consideration of the respiratory system and in our studies of clinical lesions, both etiologically and pathologically, we have been accustomed to make frequent reference to the upper respiratory tract and the lower respiratory tract. It seems obvious, however, that some additional classification and nomenclature is required for a complete understanding and appreciation of the various independent and interrelated diseases that occur so frequently in the different sections of the respiratory apparatus.

The air passages, as is well-known, begin at the vestibule of the nose and terminate in the pulmonary alveoli for inspired air, and conversely for expired air. Between these two terminals the route lends itself conveniently to a threefold anatomical and physiological classification. The nose, the accessory sinuses, and the pharynx constitute the upper respiratory tract, or, as I have chosen for the sake of convenience to call it, the *upper respiratorium*, while the trachea, bronchi, and lungs make up the lower respiratory tract, or *lower respiratorium*. Between these two divisions, and belonging to neither, lies a third the *intermediate* or *central respiratorium*, consisting of the larynx, which has a specialized and distinct function, setting it apart from the other two.

Physiologically, each division has a more or less independent and somewhat dissimilar function to perform, although they all unite in their chief object, which is to facilitate the passage of prepared pure air to its ultimate destination. The function of the upper respiratorium is a physical one, that of filtration, lubrication, and heating of the inspired air, while that of the lower respiratorium is a chemical and biological one, consisting of the delivery to the pulmonary alveoli of the prepared air for oxygenation of the blood and systemic distribution to the tissues.

Between these two sections, the intermediate respiratorium has, in the main, a mechanical function, which is carried on chiefly by the sphincter action of the glottis, which controls the quantity and pressure of the air intake, and, in addition, utilizes during expiration the latter property in the other laryngeal function namely that of phonation.

Factors Concerned in the Pathologic Sequence

There are good reasons to believe that, within the limits of the respiratory system, morbid conditions tend to pass from the upper to the lower respiratorium rather than in the reverse direction. The factors concerned in this pathologic sequence are

- 1 Aspiration of secretions with their bacterial products, by gravity and suction.

- 2 Muscular action in the pharynx, as in swallowing, hawking, etc.

- 3 Ciliary action in the upper and lower respiratoria, except in the middle and lower pharynx, where the epithelium is of the stratified squamous variety due to digestive function.

- 4 Neurogenic tonus of the sympathetic and parasympathetic systems, both of which supply the organs of respiration.

- 5 Vascular and lymphatic pathways for the spread of infection.

Aspiration of secretions. There is today experimental as well as clinical evidence that secretions pass from the upper to the lower respiratorium by simple inhalation aided by the forces of gravity.

The first author to suggest the possibility of this immediate extension of infection through the respiratory tube appears to have been St. Clair Thomson,¹ who in 1914 stated his belief that bronchorrhea might be the result of a chronic suppuration in one or more of the nasal accessory sinuses. Two years later the two French surgeons, Rist² and Sergent,³ working independently, made the observation that soldiers treated during the World War for pulmonary

tuberculosis were in a great many cases suffering not with tuberculosis but with bronchiectasis or chronic bronchitis, associated with sinus disease, and that when the sinus trouble was cleared up, the bronchial symptoms disappeared. Sergeant said that one-third of his supposed tuberculosis cases were "false tuberculosis." Rist pointed out the resemblance between the mode of infection passing from sinuses to bronchi and that which occurs in the passage of infection from bladder to kidneys. Both of these surgeons had the experience of seeing the intrathoracic disturbances clear up when the nasal trouble was corrected.

Mullin and Ryder⁴ in 1919 introduced small amounts of India ink into the nose of rabbits, holding the animals on their back with nose elevated. The experiments revealed that in all cases there were traces of ink in the nasal fossae associated with blackening of one or both lungs, when the animals were killed after periods ranging from one half hour to twenty-five days following the introduction of the ink. In two rabbits an emulsion of human tubercle bacilli was given similarly through the nose, and these micro-organisms were found, just like the ink, within the lungs some weeks later, together with a state of moderate or advanced tuberculosis. The fact that there was no ink in the mesenteric nodes, but an abundance in the bronchi and lungs, made it evident to the authors that the lung findings in this series of experiments were in all cases due to pure uncomplicated inhalation or aspiration and not to lymphatic transmission.

Quinn and Meyer⁵ in 1929 introduced iodized oil into the nostrils of sleeping patients with a view to proving whether aspiration occurs into the lower respiratorium. In five of eleven such patients there was direct evidence that the oil thus introduced was aspirated into the lung parenchyma or the bronchi with the greatest ease, and this occurred repeatedly in two of the individuals. In the other six, lack of sound sleep vitiated the experiment. It appears from the results in five patients that the swallowing reflex during sleep may be sufficiently inhibited for fluids to be aspirated into the lungs. These authors observed that when the person lies on his side, ideal conditions exist for drainage of the antrum of the opposite side, if he lies on his back, drainage of both antrums is favored. A large majority of the patients in question had maxillary sinusitis with frank pus, as associated with bronchiectasis.

2 Muscular Action in the Pharynx
Sinus infection never stays absolutely at home. The close proximity of the naso-

pharynx and the normal physiologic play of its muscular system makes it inevitable that such actions as swallowing, hawking, clearing the throat, etc., should invite the dissemination of morbid sinus secretions and result in colonizations within the pharyngeal mucosa. Once established here, these secretions by their irritating action cause itching and discomfort which the patient attempts to relieve by hawking, thus inviting further microbial aggression.

3 Ciliary Action Under normal conditions the ciliated surfaces do not become infected when pathogenic organisms gain access to them. The cilia are the chief mechanical factors in the drainage and defense of the mucosa. Their work is rapid, powerful, and effective, providing in the more active regions of the nose a complete exchange of the film of secretion over the surface about one in ten to fifteen minutes, and about once an hour in the inactive regions. They work independently of gravity and always in a spiral direction, removing tremendous loads of secretion with great celerity and dispatch. According to Hilding⁶ the rapidity of their beat in the human nose amounts to 250 cycles per minute. McDonald and his coworkers have pointed out that the ciliary epithelium of the respiratory tract, alone of all the visceral systems, lacks protection from its environmental contacts. It is impinged upon directly by the inspired air, which is teeming with micro-organisms, dust, and all manner of pollutions. Ordinarily these impurities do not affect the ciliated surfaces, but are easily disposed of in a short time without colonization and invasion.

But there are certain abnormal conditions under which this invasion may occur—conditions which establish a *locus minoris resistantiae*—and the whole system may then be thrown out of gear. Among these conditions is exposure to cold air, which, being dry, may paralyze the cilia by dehydration and by vasoconstrictor reflex from skin to mucosa. According to McDonald,⁷ any loss of fluid has this inhibiting effect upon the cilia. His experiments in cats and rabbits showed that, although under these conditions of cold and dryness the individual cilia may keep on whipping they do it ineffectively; they are unable to perform their normal defensive function in the nasal and pharyngeal mucosa, and take on an increased power of absorption. On the other hand, *excessive moisture* also modifies the extent and direction of ciliary propulsion, by causing gravity currents which flow above those produced by the cilia, and which take a direction determined by the shape and position of the part in question.

Thus the failure of the ciliary mechanism to perform its normal function leaves the mucosa of the upper respiratorium a prey to gravitational infective currents, tending to pass downward into the lower respiratorium.

4 Neurogenic Factors Since the respiratory system is supplied by both sympathetic and parasympathetic nerve fibers, it is necessary for these to be in a state of proper balance to assure normal functioning. A marked acceleration of ciliary action results from stimulation of the pharyngeal sympathetic, and a decided retardation from stimulation of the corresponding parasympathetic innervation, the latter having a depressant effect on the motion of the cilia. Once the coordination of these antagonistic nervous elements is broken, the defenses of the respiratorium are lost, the delicate adjustment is deranged, and there is nothing to prevent the infection that may be present in the sinuses from taking its gravitational course downward toward the bronchi. The influence exerted upon the vegetative nervous system of the entire upper and lower respiratoria through chronic nerve irritation induced by the inflamed mucosa of the nasal sinuses has not received the attention that it merits. Many of the symptoms that have been attributed to the absorption of toxic products from the infected sinuses can be laid at the door of direct nerve irritation arising from an inflamed sinus mucosa.

5 Vascular and Lymphatic Pathway for Spread of Infection By means of further experiments, Mullin and Ryder⁴ were able to observe the route taken by India ink which they now injected by puncture into the maxillary sinus in rabbits and the frontal sinus in cats, with care to inflict wounds that should serve as points of entry for the ink into the lymphatic system. After killing the animals they were able to trace the carbon deposits absorbed by the lymphatics over a route that passed by way of the submaxillary and internal jugular lymph nodes, lymph ducts, and great veins to the right side of the heart, and thence to the lungs. In repeated experiments this same course was always taken by the ink particles, without deviation. Clinically the most important lymph glands seemed to be the submaxillaries and internal jugular or carotids, the latter corresponding to the chain of deep cervical nodes in man, including the retropharyngeal. These workers were of the opinion that, irrespective of whether the infection spread by direct continuity or through the lymphatics, the most important part played in the production and maintenance of peribronchial infection was that carried out by the bronchial and mediastinal

glands. It was observed that the sequence in the extension of infection was a passage through the glands which transport the bacteria and their toxins to the bronchi and lungs, namely the peritracheobronchial, the intertracheobronchial, and the interbronchial. The first of these groups was intimately related to the trachea, bronchi, inferior vena cava, the lung surface, pulmonary artery, and the recurrent laryngeal and vagus nerves. The second group consisted of ten or a dozen small glands having anatomic relations to the bifurcation of the trachea above, to the pericardium in front, and to the pulmonary plexus and anterior surface of the esophagus, behind. The third group of glands was found completely buried in the parenchyma of the lung, where they occupied the angles of the divisions of the larger bronchi and the subdivisions of these down to the fourth rank. When enlarged these glands were seen to make pressure upon the pulmonary artery itself.

Evidence of Sequence of Disease

The evidence that certain affections of the lower respiratorium, notably chronic nontuberculous bronchitis, bronchiectasis, and bronchial asthma, have followed this sequence from the upper respiratorium is based upon a number of observed facts that make it seem conclusive.

First, the same pathogenic organisms are found in the primary foci as in the metastatic lesion of the lower respiratory tract. Chief among these is a type of pneumococcus that haunts the nasal sinuses and which is found so frequently in the infected bronchi and bronchioles of the same individual that it is impossible to suppose this to be a mere coincidence. Certain pyogenic streptococci are likewise found in the secretions of the sinuses and also in the sputum from the lower respiratorium. There is no natural route by which this bacterial flora might travel from below upward, the current is clearly set in the other direction, as has been abundantly demonstrated.

Secondly, we have clinical evidence that affections of the lower respiratorium have repeatedly improved and in many cases been entirely cured after the infection in a sinus has been cleaned up by suitable treatment. The rapidity with which this change takes place after eradication of a sinus infection argues strongly in favor of such a sequence. Some physicians, failing to find sinus trouble in a chronic bronchitis case, assume that it has never existed. No patient's statement to this effect should ever be ac-

cepted without a thorough examination of the accessory nasal sinuses. Very frequently the patient is entirely unaware that he has infected or hyperplastic sinuses, he has no symptoms. A chronic sinus infection may be of such low grade that it gives no discomfort, and yet a careful examination may reveal its existence. Especially in children will a careful search for sinus disease in the early days of a persistent bronchitis frequently reveal the origin of such cases. The removal of foci within the sinuses will in many cases bring clinical relief even where, as in bronchiectasis, anatomic cure is not to be expected.

Thirdly, it may be possible to prove that an infection has come down from the upper respiratorium to the lower, by inoculating into animals the pathogenic organisms obtained from smears of the nose and sinuses, on the one hand, and from the sputum, on the other, and then comparing the results. Bacteriological and serological tests may also give useful information, serving to establish the identity of the infective agent in sinuses and lungs.

Fourthly, the frequency with which an infectious disease is found to exist simultaneously in both the lower and upper respiratoria cannot be regarded as an accident, but is evidence that an infection at work in one locale has sent its emissaries, as it were, to found a colony in another region. Thus, the common diseases of childhood notably measles, scarlet fever, and whooping-cough, are frequently complicated at the same time by both sinusitis and bronchitis. An acute infection of a sinus complicated by bronchitis always leaves permanent pathologic changes in the mucosa involved, making the patient susceptible to further attacks of the same infection which may arrive simultaneously. One should not, however, let the general systemic condition distract the attention from a primary sinusitis.

Predisposing Factors

In every infection carried from a sinus to the lower respiratorium there are certain predisposing factors. I have pointed out in a previous communication⁸ that subjects in a state of general debility, with a weak constitution and a lowered state of resistance, find themselves unable to cope with an attack of infection. Especially is it true that children who have been reared under unfavorable conditions with complete absence of hygienic care, or who have been victims of nutritional deficiency from their birth, are ill

adapted to bear these attacks, and it is in such cases that we see the most serious results of secondary infection. Such children are said to go from one "cold" to another, what they really do is to go from one acute attack of sinusitis to a grave bronchitis or bronchiectasis, then, not long after the latter has quieted down a little, along comes another flare-up, a fresh "cold," inciting anew the whole train of symptoms in the lower respiratorium.

The child who is a mouth-breather because of some obstructive condition in the nasal passages is especially prone to these repeated attacks, because the air-chambers in his head do not function properly, he is not adequately ventilated. His chest muscles are flabby, his thorax contracted, his metabolism poor. The negative pressure (suction) resulting from the sweep of the air through his mouth and down his pharynx encourages a hyperemia of adenoid tissue, occluding the postnasal space, interfering with his Eustachian tube and his soft palate, and causing a disturbance of circulation in his nose and nasopharynx. His mouth is dry, his cilia cannot transmit the necessary moisture and warmth, the air he breathes is cold and unfiltered, it chills his lungs, depresses his circulation, and fails to oxygenate his blood properly. This is the type of child that most readily develops a sinus infection which is liable to lead promptly to bronchitis if not to pulmonary tuberculosis. He is the victim of every disease that comes his way, he runs from one illness to another.

A very special class of adults who easily contract these diseases of the respiratoria are the workers in stone, coal, silica or other dust-producing occupations. The sharp spicules of stone or minute bits of coal become imbedded in their pulmonary tissues or their nasal passages, where they act as constant irritants. These particles sometimes become wedged between the epithelial cells, they even enter the walls of the lymph nodes of the lungs and bronchi, inducing such grave conditions as silicosis, anthracosis or pneumoconiosis.

Another class of the predisposed are those individuals who have been weakened by long-standing chronic infections of sinuses, teeth, tonsils, etc. It takes

only a slight exacerbation of the infection in these septic foci to bring on a severe attack of infection in the lower respiratorium, due to aspiration or to lymphatic or vascular invasion of micro-organisms or their products

Finally, there is the local predisposition that follows in the wake of such pulmonary affections as pneumonia or influenza, which leave the subject in a weak and sensitive condition, not very fit to fight another inflammatory illness such as he has just passed through

Chief Metastatic Affections of Lower Respiratorium Resulting from Sinusitis

The principal nontuberculous infections of the lower respiratorium that readily grow out of a neglected sinusitis are laryngotracheitis, bronchitis, bronchial asthma, bronchiectasis, and pulmonary abscess

Laryngotracheitis The infective micro-organisms leaving the sinuses have traveled but a short distance when they find in the larynx or trachea a weak spot where they can successfully colonize. As we have already seen, it is not difficult during sleep for infective material to sidestep the esophagus and choose instead to explore the recesses of the trachea. Chronic laryngotracheitis is almost always due to the direct inhalation of septic or toxic material from a sinus, or to the direct extension of an atrophic process from the nose and nasopharynx

Mirror laryngoscopy as a rule reveals the presence of chronic laryngotracheitis, while a thorough examination of the chest shows no outstanding pulmonary disease. All systemic examinations are negative, but upon careful examination of the paranasal sinuses a chronic infection is disclosed. Bronchoscopy may then reveal a chronic bronchitis, which is presumably an extension of the chronic tracheitis. Bronchial dilatation may not always be demonstrable by bronchoscopy or pneumonography, but in a certain percentage of cases changes are observed about the carina and bronchial spurs. These generally consist of a widening of the angle of division of the trachea or bronchi, with the carina and spurs broadened and rounded. Such changes can be inter-

preted as an enlargement of the peritracheobronchial and peribronchial lymph nodes. Chronic infection of sinuses is in fact one of the commonly accepted etiological factors in laryngotracheitis

Bronchitis From what has already been said with reference to the course of the lymph glands that carry infection from the paranasal sinuses to the lungs, it is easy to understand how these glands, when they have become enlarged, may by compressing the pulmonary artery produce a cough. It is also evident that they can make pressure upon other important structures and thereby cause retention of secretions within the finer bronchial tubes. Thus arises a metastatic bronchitis. Mullin⁹ recognized four types of sinus infection, which he called, in the order of their progressive development: acute inflammatory, acute purulent, chronic purulent, and chronic hyperplastic. The first two stay at home, so to speak, or they affect the lower respiratorium only by reflex irritation. It is the third and fourth that do the mischief. A chronic purulent sinusitis may often be highly insidious, as I have pointed out elsewhere.⁸ It may cause no pain, the discharge may be slight, there is no cough, headache nor any of the unpleasant manifestations commonly associated with disease of the sinuses. Yet the patient goes steadily downhill, he feels weak and flabby. The extensive mucous lining of the paranasal region gives a wide surface for absorption, and in the course of time the lymphatics take up the infection and carry it into the bronchial tubes, the result of which is a chronic bronchitis

In the chronic hyperplastic form of sinusitis, as recognized by Mullin,⁹ the mucosa becomes thickened and soggy, and may exhibit polypoid degeneration. There is at this stage very little drainage through the natural ostium of the maxillary sinus. The infection has become attenuated, resulting in a chronic hyperplastic condition of the sinus mucosa, nevertheless this mucosa is seriously diseased, and the absorption of bacteria and their toxic products through the lymph channels leads to chronic peribronchial glandular enlargements. The prime importance of the maxillary sinus in the production of bronchial infections lies in the fact that it develops early, its drainage is difficult

to maintain, and it is the largest of the paranasal sinuses. It therefore offers a greater surface for absorption of its infective products. The protracted flooding of the lymph channels with bacteria from this hyperplastic sinus tends to awaken a chronic peribronchitis, of which a "cold on the chest" may give the first evidence. Eventually a definite chronic bronchitis is built up.

Bronchial asthma In making nasal examinations in twenty cases of asthma, referred by a pediatrician, Lierle¹⁰ found disease of one or more paranasal sinuses in every case. In sixty per cent there was deflection of the septum, which obstructed drainage. Nasal treatment consisted in freeing the nose from every source of infection and in providing proper ventilation and drainage. A search should also be made for any local spots that might be responsible for abnormal reflexes. Mullin and Ryder⁴ point out that asthma is a symptom, and not a disease entity *per se*. They recognize three causes: (1) allergy, (2) infection in paranasal sinuses, and (3) reflex stimulation. However, all three causes may act together. It is usually the hyperplastic rather than the purulent type that causes bronchial asthma, the type that produces a luxuriant growth of polyps to act as irritants. In some cases removal of the polyps stops the asthma, when they grow again, the asthma returns. This happens too frequently to be an accident. The maxillary sinus may contain a low grade, dormant infection, which changes with the seasons, free from spasm in summer, but irritated again in winter.

Sluder¹¹ reminds us that the sympathetic nervous system in the nose is derived from the nasal ganglion, that it receives its sympathetic nerve supply from the vidian nerve, the great deep petrosal, the carotid plexus, and the upper cervical ganglion. Impulses may be transmitted from the inflamed nose by way of the nasal ganglion, the vidian nerve and carotid plexus to the sympathetic trunk in the neck, and thence to the lower cervical and first thoracic ganglia, thus proving that asthma may be a nasal reflex, dependent on the irritation of hyperplastic nasal tissue. Draining of the sinuses often cleans them up. Coates¹² thinks there is a bacterial allergy here, and that there is

little doubt that attacks of true allergic asthma are often precipitated by accessory sinus infection. On the other hand, nonallergic asthma is often due in his opinion to the direct irritation caused by contact of infected secretions from the nose with the tracheal and bronchial mucosa.

Bronchiectasis After a chronic bronchitis has become established, from a sinus infection, it will, if neglected, nearly always go on to a bronchiectasis, which of course is anatomically a permanent condition. Quinn and Meyer⁵ found bronchiectasis in twenty-two (58%) of thirty-eight patients with chronic bronchitis from sinusitis. It was long before it was generally recognized that some patients having symptoms of pulmonary tuberculosis, but with negative sputum, had no tuberculosis but were suffering with bronchiectasis. In a great many of these cases there are no symptoms of sinusitis, it is only very careful examination that brings out the fact of its existence. Webb and Gilbert,¹³ who made roentgenograms of the accessory sinuses in all cases of chest disease without tubercle bacilli, assert that there were but few cases of bronchiectasis or chronic bronchitis in which the x-rays did not bring out the presence of chronic sinusitis. In most cases they found bilateral empyema of the antrums and sometimes a state of pansinusitis.

The association of sinus disease with bronchiectasis is too common to be a chance finding, it is almost systematically conjoined with the latter. Clerf¹⁴ says it is so usual to find it that he prefers in all cases to consider that sinusitis is present until a rhinologist proves the contrary. He regards it as a very important predisposing cause in the production of bronchiectasis—a predisposition brought about by the enlargement of the peritracheal and peritracheobronchial lymph nodes, which interferes with the normal motility of the tracheobronchial tree, and by the occurrence of a low grade inflammatory reaction of the larynx, trachea, and bronchi, which is productive of excessive mucoid secretion and interferes with ciliary activity. These factors, together with susceptibility of the patient to "head colds," increase the frequency of acute bronchopulmonary infections, which in turn are responsible for bron-

chiectasis. It even appears that there is a very common association of sinus infection with bilateral lower lobe bronchiectasis, for which no adequate explanation has been found.

Pulmonary abscess. There is a great deal of evidence that pulmonary abscess is in a substantial percentage of cases due to aspiration of infected material from the upper respiratorium. Thus Freedlander,¹⁵ in a study of 238 cases of pulmonary abscess observed at the Cleveland City Hospital, found that in 141 cases (55%), the history was such as to make aspiration appear to be the probable cause. There is a type with a long history of chronic pulmonary suppuration, probably bronchiectatic, which at some time flares up with signs of acute abscess, that belongs in this class. At all events, many of the older cases had a complicating bronchiectasis.

Lueh and Sutton,¹⁶ in analyzing clinical material of 101 cases of lung abscess, found that in thirty per cent the abscess had been preceded by infections of the upper respiratorium. In one-third of the cases bronchoscopic examination revealed a swelling of the affected mucosa or extensive granulations. Patients who complain of pain in the chest and of expectoration a few weeks after an acute infection of the upper respiratorium—an attack of pneumonia or an operation about the nose and mouth—should be suspected of having a lung abscess.

One of the most convincing proofs in favor of an aspiration theory is the invariable existence of a communication between the abscess cavity and a bronchus, this communication is a direct continuation of a bronchus, and the abscess cavity is lined with epithelium which is continuous with that of the bronchus.

Ochsner and Nesbit¹⁷ observed that after a peritonsillar infiltration with procaine, iodized oil taken into the pharynx passed directly into the tracheobronchial tree, if oil can go there, it is clear that peritonsillar infection could take the same

route during anesthesia. According to these authors, general anesthesia produces an immobility of the larynx which prevents it from rising to a point of safety beneath the base of the tongue and epiglottis.

Flick¹⁸ and his coworkers reported that in forty-three of 172 cases (25%) the pulmonary abscess followed an acute infection of the respiratory tract, in twenty-two this was called "an acute cold," "influenza" or "acute bronchitis." In 121 cases the abscess followed operations, ninety-seven of which were tonsillectomy, while ten were of an oral nature.

It is evident, therefore, that these localized abscesses are in a very large number of cases the result of infection that has found its way down from the upper respiratorium. Where the lung abscess has been preceded by a recent tonsillectomy the sequence is too obvious to be overlooked.

Summary and Conclusions

1 The air passages fall naturally into three sections—an upper, a central, and a lower respiratorium, each having its own special function.

2 In the passage of infection from the upper to the lower respiratorium, there is a pathological sequence based on natural law.

3 The principal factors concerned in this sequence are aspiration, muscular and ciliary action, neurogenic balance, and the lymphatic and ciliary pathways by which infection is spread.

4 The paranasal sinuses, in their strategic position at the head of the respiratory tube, are the key to the transmission of practically all the infectious diseases to which the respiratory system is subject.

5 The sequence of infectious disease in the respiratory apparatus is from the sinuses downward toward the bottom of the respiratory tree.

Case Report

NON-PENETRATING WOUND OF THE HEART

Injury to the Pericardium and the Left Pericardiophrenic Artery with Near Fatal Hemorrhage

M L LEVY, MD, FACS, Brooklyn

From the Surgical Department of Beth Moses Hospital

The seriousness as well as the differential diagnosis, and the urgent treatment that non-penetrating wounds of the heart may require, is well-illustrated in the following protocol

A Negro, aged seventy-two, was brought into the emergency room of the hospital about five minutes before I arrived to operate on another patient. He was unconscious, extremities cold, pulseless at the wrist, but breathing. There was a small wound, three-quarters to one inch in width, in the fourth intercostal space, several inches to the left of the sternum, caused by a knife thrust. There was no evidences of air escape from the wound nor was there any bleeding. Irregular sounds were heard, but no regular sustained heart beats, on listening over the precordia. Over the greater portion of the left chest flatness was percussed. Auscultation over this latter area revealed absence of breath sounds. The house officer, properly impressed with the urgency of the situation, refused to allow the patient to be completely disrobed, or even moved to a bed in the ward. Heat was applied to the body and the extremities. A venoclysis was started at once. In this fashion the patient was immediately, though tenderly, transported to the operating room, and hurriedly prepared. The operating room was already set up, the nurses prepared and waiting. No anesthetic, except a hurried superficial linear injection of one percent novocain solution at the site of the proposed incision, was employed.

An intercostal incision was made in the left fourth interspace, the sternal end of the cut passing abruptly downwards over the sternum for several inches. About four inches of the fourth rib with its costal cartilage was removed. The left sternal margin in this interspace was gouged out with rongeur. Before the pleura was incised, pulmonary insufflation by positive pressure,

using oxygen, was employed. The left pleural cavity was filled with blood. Suction was employed to remove the blood, to view better, the interior of the thorax, as well as the condition of its contents. The ribs were retracted with small sized right angled retractors, as a substitute for regular rib spreaders. The lung was undamaged. On the pericardium, to the left and somewhat posterior just below the left auricle there was a small clean cut wound, where the knife had punctured the pericardium, severing the left pericardiophrenic artery. This vessel was intermittently still spurting with each weak beat of the heart, pouring its blood directly into the thoracic interior. The artery was sclerotic, coursing in a perfectly straight line, diagonally, from above downwards and backwards. Interrupted fine chromic catgut, on needle, placed about the artery and tied above and below the opening in the vessel, immediately stopped the bleeding. A separate opening was then made in the pericardium and the interior viewed.

There was no apparent gross damage to the myocardium. A very small amount of blood was in the pericardial sac. Fine chromic catgut material was used to close the rents in the pericardium. During all this time the patient's condition continued poor, pulseless, cyanotic, and every inspiration appearing his last, but nevertheless, he continued to breathe. But once the severed vessel was ligated, the picture changed. Directly a "flicker of a pulse" was reported by the anesthetist, and hopes for his recovery were entertained. The venoclysis, that had been continued uninterruptedly throughout, was soon followed by a blood transfusion without a break in the flow. The pleura with the intercostal muscles were approximated, the latter with heavy chromic catgut interrupted sutures, the skin closed with

black silk, making a fairly good airtight closure of the thorax. The pulmonary insufflation was discontinued. The improvement was progressive, with a betterment in the pulse, color, and breathing. The patient returned to semi-consciousness and attempted to struggle. With gradual returning consciousness and coincident betterment in the quality of the pulse and general condition, the patient was sent to his bed in the ward. He was restless, and often had to be restrained, but had lucid moments. With the return of full consciousness he became cooperative.

Directly following the operation there developed signs and symptoms of left sided pleuroperitoneal irritation, with rigidity of the muscles of the left chest and left side of the abdomen, tenderness and pain on movement of these muscles, dyspnea, rise in temperature, abdominal distention, and inability to retain food. The white cell count in the blood, taken at this time, was 16,200 with ninety percent polymorphonuclear leukocytes and ten percent lymphocytes. Surprisingly enough this symptom complex almost completely disappeared in four days. The heart, throughout, had remained markedly displaced to the right, its sounds diffuse, rapid, but fairly regular.

Physical signs, confirmed by x-ray findings, showed evidences of considerable blood still remaining in the left chest, as well as fluid in the pericardial sac. The pericardial

cavity was aspirated twice, yielding on each occasion about fifty c.c. of light straw-colored fluid. The needle, in each instance, was introduced in the sixth intercostal space, close to the right of the sternum. About eight ounces of blood was removed from the left chest about a week following the operation, and although, later on, evidences of fluid in the chest still existed, no attempts at its removal were deemed wise or necessary. Dyspnea and an annoying sense of chest constriction were greatly benefited by the above measures. Cough and expectoration lasted for several weeks. The fluid removed from the pericardial cavity, on culture, showed no organisms. The blood pressure varied from ninety systolic and thirty diastolic taken several hours following the operation to 132 systolic and eighty diastolic one week later. The Kahn and Wassermann tests of the blood were negative. Further x-rays, taken at intervals, showed a slowly shifting heart back towards the left, the heart and mediastinal contents gradually attaining a more anatomical relation with a progressive absorption of fluid in the left chest. The electrocardiograph, taken before the patient's discharge from the hospital, was not remarkable. In three weeks, with his wound healed, he was allowed on a chair for a short period of time and two weeks later was well enough to be discharged from the hospital.

856 PROSPECT PLACE

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B. LIBER, M.D., D.R.P.H., *New York City*

Editorial Note: Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Smart Aleck

A young man of the acutest intellectual type came to the clinic reluctantly. He claimed not to need the doctor. He "had heard of him and just wanted to have a talk about things in general." That meant, of course, he was struggling against the idea of being treated. He vaguely knew he was not well, but would not admit it to himself. He thought he would deceive the physician as he deceived himself and perhaps glean from the conversation with him some hints that will help him keep among the healthy.

So he spoke about psychology and seemed to have some theoretical problems to solve that "had nothing to do with himself." But willy-nilly his "psychology" dropped into

somatology, that is his mind was soon translated into body functions, which made the medical interlocutor think of a psychoneurotic.

Then he enlarged on psychoanalysis and juggled with its vocabulary in a cleverer way than most specialists would be able to do. The torrent of phrases gushed so fast that nobody could have put in a word. But in a brief moment of silence the doctor timidly suggested that this was "too much Freud," more than Freud himself would accept, that it amounted to adapting facts or symptoms to theory, changing the most modern system into something medieval and so going back to pre-Baconian times. This puzzled the sophisticated man and he

changed the subject, now speaking about himself, so much so that one's diagnosis had to be modified as one was put on the track of a schizoid mentality, perhaps of an unusual form, but in principle the same as others. As he was encouraged to go on, he revealed indeed his chief symptom, by expressing the belief, first as if it were dealing with everybody, then referring it to himself, that he had no existence in reality, that his ego had vanished and that he was but a "reflection" of his surroundings—a frequent utterance in such individuals. He mentioned Schopenhauer, also a favorite author of people with similar psychotic tendencies. But he was immediately told that the comparison did not fit, since in *Die Welt als Wille und Vorstellung* the world was rather a reflection of ourselves—in fact, the world would not be without a human mind to conceive it.

At the second visit he had eructations like any ordinary mortal and I elucidated that he was as constipated as any self-respecting American and taking all the purgatives advertised everywhere which interfere so much with a cure. His speech was a step further advanced in schizophrenia, except that it showed in addition the mind of the constipated person. He challenged the doctor to prove that he, the patient, was alive and asked how can one be aware of oneself. Descartes' *Cogito, ergo sum*, quoted to him, seemed to make no impression. He was not convinced that he was thinking or that the thoughts he expressed were his own.

One important cue was given by his sex situation. Although surrounded by flattering girls, he was indifferent to them. Nor was he a homosexual.

In due course of time he had to admit, both to himself and to the doctor, that he was and should be a patient. His condition was bad but not hopeless.

Although he became more modest and docile as he continued to face the doctor, he still had outbursts of "superiority" once in a while, either in his line as a budding literary man or in his, now decaying, devotion to spiritism. It was easy to persuade him of the inaccuracy of the latter as a "science" and to demonstrate to him that conviction is often the result of will. Many instances were given. The one that impressed him mostly was the story from the doctor's Parisian high school days, almost fifty years before, when children used to

play finding a concealed object by holding the hands of one who knew where it had been put. The latter, unknowingly, unwillingly, led the searcher to the hidden thing by minute and hardly perceptible, but sufficiently palpable motions. Our patient felt visibly ashamed when told that boys of thirteen or so had been enlightened for life and had become immune to nonsense and superstition due to a game. With this small example as a basis the idea was extended into larger and weightier matters until the patient was conquered and rendered docile.

As a writer this patient commanded the admiration of the younger set of readers, especially those with pretensions to extreme and exclusive abstract and modernistic tastes and who never guessed how ridiculous they were. He knew his customers and had carefully studied how to strut and shine, how to *épater le bourgeois* and to impress by mentioning names from Dadaist, Surrealist, and Post-Impressionist art and literature. He was careless about the spelling of foreign words and superior to correctness of scientific facts, as many upstart and arrivist writers are. Hence his success, which was even more promising for the future—if it had not been checked by his mental condition.

He had begun to withdraw from his cénacle, because his sociability was cracking from all sides. But he was yet, in spite of himself, the center of an adulating circle, which was irritating and obnoxious to him, and he was led to abandon his friends entirely.

Then he was shown the emptiness of his position, the lack of foundation, the superficiality and untruthfulness of his literary life, about which he himself subconsciously knew and which was largely the cause of his unhappiness and his lack of satisfaction with himself. That, added to his congenital mental trend, explained the etiology of the case. At bottom he was and wanted to be honest and hated snobbishness, so he accepted these suggestions.

There was difficult, uphill work, but finally he was able to wipe out a good deal of his inner conflict. Then he did not disdain to accept work as an obscure and unnamed hack in a publishing house. His preferences kept on changing until he aspired to write a plain short story book descriptive of life as it was.

EDITORIALS

Same Work, Same Ethics

The essential considerations in the practice of medicine, whether by a group of physicians or an individual, are always the same. The patient must be assured of the skill and integrity of his doctor or doctors. The medical man must be governed, first by his responsibility toward those under his care, secondly by consideration for his fellow practitioners. Whether he practices singly or in association with an organized group, the same principles of professional conduct should guide him in the discharge of his obligations.

There is no more reason or excuse for groups of doctors to advertise than for individuals. A reputation for able, honest service is still the best recommendation for any practitioner and the safest guide for the public. There are the same dangers to the laity in group advertising as in the sensational self-aggrandizement of men practicing singly.

Physicians do not lose their duty to the rest of the profession by banding themselves in groups. They are still bound to refrain from unfair competitive practices designed to advance their little bund at the expense of the remaining medical men in the community.

Contrary to expectations raised chiefly

by lay propagandists, the popular demand for group service has not materially increased. Neither has group practice on the average surpassed the quality of individual practice.

There is therefore no excuse for granting group practitioners special privileges. For continued public protection the Medical Society of the State of New York adheres to the policy "that groups of physicians, practicing as such, should remain within the same framework of restrictions as to their conduct as though the activity were that of an individual physician."

Mathematical Magic

Harold F Clark, Professor in charge of Educational Economics at Teachers College, Columbia University, has pulled a strange rabbit out of his mortar board. By means of no one knows what mathematical necromancy, he has fixed the monetary value of the average medical career at \$108,000 00. This figure takes into account a four per cent discount for cash. It surpasses any other of the sixteen vocations cited.

With a cash value of over a hundred thousand dollars, it is not surprising that medicine takes the lead. The surprising

thing is that after eight years of study Professor Clark should have reached a figure so incompatible with the facts and in such marked contrast to the results of other surveys

The Professor does not reveal the yardsticks by which he measures income, so that it is difficult to refute his statistics with precision. He does not, for instance, say whether his \$108,000.00 represents net or gross income, an important point in comparisons with professions like teaching, in which salary is net income. He also neglects to mention whether his total for farm labor includes maintenance, which hired help generally receive, or foods raised for personal consumption, which are normally part of farm income.

Professor Clark's mathematical conjurations would not deserve serious attention if it were not for the publicity given to his conclusions. "From the standpoint of society at large, income is the best measure we have of the relative need in all socially desirable occupations. It consequently follows that people should be encouraged to go into occupations that have incomes above the average and to stay out of all occupations where incomes are below the average."

Professional service is a type of service that people are willing to pay more for because it is scarce."

It does not seem to occur to the Professor that the question of fitness is more important in a profession like medicine than potential earnings, or that some forms of service earn more than others because of the greater degree of skill required and the longer period of preparation they entail. Higher earnings in such cases do not necessarily indicate a lack of practitioners to supply the public demand.

It is impossible to fathom by what criterion Dr. Clark places medicine at the financial head of the vocations he cites. Every responsible survey in recent years has remarked upon its poor economic return. The Professor's stab at medical earnings appears as exaggerated as his

guess of forty-two years as the working life span of physicians.

A student who entered medical college on the strength of the Clark statistics would be keenly disappointed by what he found. The physician who earns more than a simple livelihood is the exception rather than the rule. Medicine never has been "tops" as a money making profession. Professor Clark's figures notwithstanding, it's the last occupation in the world for financially inclined go-getters.

Combination Therapy of Anemia

It is known that the body requires a constant supply of certain substances in order that erythropoiesis may proceed normally. Among these, iron, copper, and the substances present in whole liver are the most important. The role of thyroxine, chlorophyll, and the pituitary secretion are undetermined factors in maintenance of adequate red-cell production.¹

A deficiency of the required factors, be it the result of faulty diet, metabolic disturbance or organic disease, will produce an anemia. Following the administration of material potent in overcoming anemia, the latter can be checked in its progress and most often entirely remedied. In the treatment of secondary anemias, the pharmacological action of the various drugs and substances at our disposal must be thoroughly understood. Iron can be stored in the liver and so become unavailable for the production of hemoglobin unless liberated for use by a catalytic agent such as is to be found in copper. In addition, the extrinsic factor found in liver must be combined with the intrinsic one normally present in the gastric mucosa.

It has been demonstrated that different substances causing identical therapeutic effects are augmented in their action when administered in combination with one another. On the other hand, substances having different pharmaco-

¹ J. Vaughn, J. M. *The Anemias*, 2nd Ed., Oxford Univ. Press, London, 1936.

logical points of attack produce a still more intensified result when combined in medication. These principles, first advanced by Buerger² seem to apply in the treatment of secondary anemias. A combination of small doses of iron, liver, calcium, and Vitamins B and G was found by Almour³ to be of decided value in benefiting both the secondary anemic state and the symptoms resulting therefrom. Further investigation is, of course, desirable before it can be definitely determined whether this form of oral medication is as efficacious as the parenteral administration of hematopoietic drugs.

Glutathione in Thymus

The growth promoting properties of glutathione have been amply demonstrated. The chemical is a compound of cysteine and glutamic acid and in the body assumes the role of a catalytic agent in the oxidizing of fatty acids. Its presence in the thymus gland has been determined by chemical analysis but whether the gland manufactures it or merely stores it is as yet unknown.

Rowntree, Steinberg, and Hanson,¹ who have been conducting experiments in animals on the functions of the thymus gland, have succeeded in developing precocious rats by feeding successive generations with thymus extract. This precocity can be greatly enhanced when glutathione is substituted for the extract of the thymus.

The fact that this chemical promotes both normal and abnormal growth and accelerates cell division opens up a new field in cancer research. Abnormal growth still remains the chief problem in the investigation of cancer, the production of which may be affected by extrachromosomal influences during the embryonic stage of life.² Added investigation of the

action and function of glutathione may furnish a clue to the origin of malignant growth.

CURRENT COMMENT

"NOW WHILE IT DOES NOT INSURE health or stop illness, sickness insurance is a degradation and mental degeneration to the insured.

"The duly protested Japanese invasion of American industry is small time marbles compared to the politician's invasion of the sacred science of medicine—sacred because of its traditions, its purposes and its essential honor.

"Any system that tends to lower and even actually to abase any unit of civilized life that both protects and develops the mental, moral and physical perfection of the populace is an odious, even a vicious visitor to the American nation"—Vehement editorial comment, to be found in the *Illinois Medical Journal* of July 1937.

"IT DEEMOIVES THE MEDICAL profession to formulate a program which will leave the control of medical care in the hands of the profession and yet continue to provide adequate medical care to all classes. Perhaps this is easier said than done. However, it is a challenge we must eventually accept"—Dr. A. C. Hansen, writing in the *Supplement* to the *Saint Louis County Medical Society Bulletin*, July 1937.

"THE LATELY INSTINCTIVELY has respect for the things that doctors wives say and do. They are influential, whether they will or not. Doctors' wives truly have married not alone into close contact with the men they love—but into the great profession itself"—From the *Jackson County Medical Journal* of recent date.

"THE ENTIRE THREAT OF SOCIALIZED or state medicine is made possible by a sense of false security in hospital directors and in doctors themselves. If socialized medicine should ever become a reality, doctors must blame themselves if they are forced to view the ruins of a great edifice with the mumbled explanation 'We were not prepared'"—An opinion and a warning by *The Linacre Quarterly*.

² Puergel *Med Biol* Schrefflen 4 25 1932

³ Almour, H. N. *STATE J MED* 37 1283 1937

¹ Rowntree L. G. Steinberg, A., and Hanson A. *Science* 84 9 1936

² Little, C. C. *Proc Staff Meet Mayo Clinic*, 11 782, 1936

"A MIXTURE OF MISERY AND education is highly explosive."—Sir Herbert Samuel, quoted in *The Digest* of July 24

"THERE SEEMS TO BE NO DOUBT that the methods of training the medical student call for revision and reform and it is equally patent that the question simply bristles with difficulties. Not only is the training defective in some respects and the curriculum overloaded but more opportunities are necessary for the newly qualified man to gain practical experience before entering upon practice. There are signs that the practice of medicine is changing and it is essential that medical practitioners should not be found wanting when changes come. The curriculum must be so framed as to turn out medical men able to cope with any condition or situation"—A comment on "The Medical Curriculum" by the editors of *Medical Record*, July 21

"FOR SOME TIME WE HAVE OPPOSED the propositions and principles of State Medicine in these columns. We have felt that State Medicine is essentially contract practice, and as such, not in the interest of the people or of the physician. We viewed the State in the light of employer and paymaster unfavorable. We envisioned the physician under contract to the State, almost as a convict of the unenlightened days, slaving his life out in leg irons under the cruel lash of the overseer, at the behest of ruthless politicians.

"Our pineal or mind's eye which we reserve for special editorial use on hot days,

created a picture of predatory politicians with unkempt hairy hides like wolves, offering degrading contracts to emaciated physicians whose private practices had been undermined by welfare termites and philanthropic-looking red ants. Isn't it terrible to have a mind's eye like that?

"However, it is a great relief to admit that we were wrong. Almost like waking up out of a nightmare! Our hideous phantasies vanish, and our pineal, or mind's eye which we reserve for special editorial use on hot days is blacked, deservedly, by the hard and bony fist of truth and reason. We read (p 122, *Med Econ* May 1937), that 'For \$1,400 a year, out of which he had to pay for all his medical supplies, an Illinois doctor contracted to care for the poor of a medium-sized city. At the end of a year he found that he had pulled 542 teeth, had performed five hysterectomies and 72 other abdominal operations, and had attended 55 obstetrical cases. Also, he had 5,703 office visits, 3,223 residence calls, 66 visits to the county home, 57 police calls (fifteen to the county jail) and 177 calls to rural districts from eight to 23 miles away'.

"In view of these facts, our apprehensions for the physician under State Medicine are seen to be plainly unfounded and illusory. We now see that they should have been reserved for his patients, for no physician with so much money to squander could be expected to keep his mind on his job"—We enjoyed reading the above editorial from the pen of Laurance D Redway, M.D., in the July *Westchester Medical Bulletin*, and so we have quoted it in full.

Correspondence

In Memoriam Dr John Henry Wyckoff

1136 Fifth Ave,
New York City

To the Editor

Dr John Henry Wyckoff in making his academic career through his active connection with the New York University Medical College was well-known to American Medicine. Having followed his work, and his intellectual endeavors in the interest of the advancement of medicine, he was known to me in spirit and through occasional contact

at the bedside. Two years ago, however, the opportunity for closer relationship presented itself. At that time the extra-mural plan of teaching was extended to include the medical department of Beth Israel Hospital and students have been sent to us from the College for elective courses in internal medicine.

Doctor Wyckoff, as Dean of the Medical College was vitally interested in every phase of the students' medical progress and it was

natural for us to have a more intimate association with him than was possible before.

There grew upon me rapidly a realization of the greatness of the Dean's personality and the earnestness with which he devoted his life to the teaching and practice of medicine. These qualities so impressed themselves upon me that I am impelled, in this hour of his sad passing, to give humble expression to my own personal feeling. I do this not only in tribute to the memory of a great teacher, but also to bring him more intimately to those whose duty it will be to carry on his precepts.

He was a man of a minimum of words and a maximum of action, and it was characteristic of Dr. Wyckoff to put into action his accomplishments after thorough deliberation and discussion with those whose advice he needed as vital to the cause, and not to make public his plans until they were launched. His writings also show his habit of careful thinking and his logical approach to a conclusion. Indeed, they reflect the kind of man he was: the clinician who, at the bedside—where throughout many years I had occasions to meet him—could with penetrating insight as well as with remarkably few words recognize the truth. He understood patients because of an innate, profound self-identification with all other human beings, and into his teaching of students he carried that intuitive understanding.

Appreciating the need of large buildings, he often expressed the desire for such a realization. But his ambition to have great teachers in their respective branches was even greater than to have large impressive buildings. The latter task he carried out with all the mental and physical strength that was in him. Wyckoff was partial only to accomplishment. Nothing else actually counted with him. The success with which he worked out his plan in the development of his school is now widely known. In large measure it was due to the Dean's personal efforts, on the basis of the foundation

laid by his predecessors, Egbert Lefevre and Samuel Brown, who stressed the importance of a liberal practical school without in the least sacrificing the scientific aspects.

Wyckoff realized actually what the late Peabody of Harvard had planned but did not live to carry out, namely, that there must be two classes of teachers in a medical school, the one more purely scientific such as the chemist and the physiologist, and the other, the clinical teacher who, although himself not endowed with the quality of doing original experimental work, nevertheless, knows how adequately to evaluate it and apply the findings at the bedside. He went further and developed to an extraordinary degree an integration of the clinical and more purely scientific branches to the great advancement of both.

Freedom for the teacher to use his own method of teaching was the primary principle of practice insisted upon by Dean Wyckoff. Nevertheless with his keen eye and mind he supervised sufficiently so that all departments should work harmoniously. He wished the students to have diversified viewpoints but they must be of the truth, and not those that may cause confusion. His untimely death has robbed the college, the hospitals and American medical education of a great leader. The only mitigation of this loss is the fact that through his greatness he planned so well that the principles for which he stood cannot fail to be maintained. No one can ever quite take his place in the hearts of all who loved him but he built so well that the mantle of his personality and ability remain as constant inspirations and guides to those who must carry on in his place to the eventual full realization of John Wyckoff's ideal. For all of us, there is left the precious memory of an association with one who epitomized all that we strive and hope to be.

I W. HELD, M.D.

July 2, 1937

DISTRICT BRANCH MEETINGS

The Annual Meetings in 1937 will be held this fall on the following schedule

Sept. 21	Sixth District Branch	at Owego
" 22	Seventh " "	" Geneva
" 23	Fifth " "	" Lowville
" 30	Third " "	" Kingston
Oct. 1-2	Fourth " "	" Glens Falls
" 5	First " "	" New York City
" 7	Eighth " "	" Olean
Nov. 17	Second " "	" Garden City

"A MIXTURE OF MISERY AND education is highly explosive"—Sir Herbert Samuel, quoted in *The Digest* of July 24

"THERE SEEMS TO BE NO DOUBT that the methods of training the medical student call for revision and reform and it is equally patent that the question simply bristles with difficulties. Not only is the training defective in some respects and the curriculum overloaded but more opportunities are necessary for the newly qualified man to gain practical experience before entering upon practice. There are signs that the practice of medicine is changing and it is essential that medical practitioners should not be found wanting when changes come. The curriculum must be so framed as to turn out medical men able to cope with any condition or situation"—A comment on "The Medical Curriculum" by the editors of *Medical Record*, July 21

"FOR SOME TIME WE HAVE OPPOSED the propositions and principles of State Medicine in these columns. We have felt that State Medicine is essentially contract practice, and as such, not in the interest of the people or of the physician. We viewed the State in the light of employer and paymaster unfavorable. We envisioned the physician under contract to the State, almost as a convict of the unenlightened days, slaving his life out in leg irons under the cruel lash of the overseer, at the behest of ruthless politicians.

"Our pineal or mind's eye, which we reserve for special editorial use on hot days,

created a picture of predatory politicians with unkempt hairy hides like wolves, offering degrading contracts to emaciated physicians whose private practices had been undermined by welfare termites and philanthropic-looking red ants. Isn't it terrible to have a mind's eye like that?

"However, it is a great relief to admit that we were wrong. Almost like waking up out of a nightmare! Our hideous phantasies vanish, and our pineal, or mind's eye which we reserve for special editorial use on hot days is blacked, deservedly, by the hard and bony fist of truth and reason. We read (p 122, *Med Econ* May 1937), that 'For \$1,400 a year, out of which he had to pay for all his medical supplies, an Illinois doctor contracted to care for the poor of a medium-sized city. At the end of a year he found that he had pulled 542 teeth, had performed five hysterectomies and 72 other abdominal operations, and had attended 55 obstetrical cases. Also, he had 5,703 office visits, 3,223 residence calls, 66 visits to the county home, 57 police calls (fifteen to the county jail) and 177 calls to rural districts from eight to 23 miles away.'

"In view of these facts, our apprehensions for the physician under State Medicine are seen to be plainly unfounded and illusory. We now see that they should have been reserved for his patients, for no physician with so much money to squander could be expected to keep his mind on his job"—We enjoyed reading the above editorial from the pen of Laurance D Redway, M.D., in the July *Westchester Medical Bulletin*, and so we have quoted it in full

Correspondence

[THE JOURNAL reserves the right to print correspondence to its staff in whole or in part unless marked private. All communications must carry the writer's full name and address, which will be omitted on publication if desired. Anonymous letters will be disregarded.]

In Memoriam Dr John Henry Wyckoff

1136 Fifth Ave.,
New York City

To the Editor

Dr John Henry Wyckoff in making his academic career through his active connection with the New York University Medical College was well-known to American Medicine. Having followed his work, and his intellectual endeavors in the interest of the advancement of medicine, he was known to me in spirit and through occasional contact

at the bedside. Two years ago, however, the opportunity for closer relationship presented itself. At that time the extra-mural plan of teaching was extended to include the medical department of Beth Israel Hospital and students have been sent to us from the College for elective courses in internal medicine.

Doctor Wyckoff, as Dean of the Medical College was vitally interested in every phase of the students' medical progress and it was

natural for us to have a more intimate association with him than was possible before.

There grew upon me rapidly a realization of the greatness of the Dean's personality and the earnestness with which he devoted his life to the teaching and practice of medicine. These qualities so impressed themselves upon me that I am impelled, in this hour of his sad passing, to give humble expression to my own personal feeling. I do this not only in tribute to the memory of a great teacher, but also to bring him more intimately to those whose duty it will be to carry on his precepts.

He was a man of a minimum of words and a maximum of action, and it was characteristic of Dr Wyckoff to put into action his accomplishments after thorough deliberation and discussion with those whose advice he needed as vital to the cause, and not to make public his plans until they were launched. His writings also show his habit of careful thinking and his logical approach to a conclusion. Indeed, they reflect the kind of man he was: the clinician who, at the bedside—where throughout many years I had occasions to meet him—could with penetrating insight as well as with remarkably few words recognize the truth. He understood patients because of an innate, profound self-identification with all other human beings, and into his teaching of students he carried that intuitive understanding.

Appreciating the need of large buildings, he often expressed the desire for such a realization. But his ambition to have great teachers in their respective branches was even greater than to have large impressive buildings. The latter task he carried out with all the mental and physical strength that was in him. Wyckoff was partial only to accomplishment. Nothing else actually counted with him. The success with which he worked out his plan in the development of his school is now widely known. In large measure it was due to the Dean's personal efforts, on the basis of the foundation

laid by his predecessors, Egbert Lefevre and Samuel Brown, who stressed the importance of a liberal practical school without in the least sacrificing the scientific aspects.

Wyckoff realized actually what the late Peabody of Harvard had planned but did not live to carry out, namely, that there must be two classes of teachers in a medical school, the one more purely scientific such as the chemist and the physiologist, and the other, the clinical teacher who, although himself not endowed with the quality of doing original experimental work, nevertheless, knows how adequately to evaluate it and apply the findings at the bedside. He went further and developed to an extraordinary degree an integration of the clinical and more purely scientific branches to the great advancement of both.

In Memoriam Dr. John Henry Wyckoff

1136 Fifth Ave.,
New York City

To the Editor

Dr. John Henry Wyckoff in making his academic career through his active connection with the New York University Medical College was well-known to American Medicine. Having followed his work, and his intellectual endeavors in the interest of the advancement of medicine, he was known to me in spirit and through occasional contact

at the bedside. Two years ago, however, the opportunity for closer relationship presented itself. At that time the extra-mural plan of teaching was extended to include the medical department of Beth Israel Hospital and students have been sent to us from the College for elective courses in internal medicine.

Doctor Wyckoff, as Dean of the Medical College was vitally interested in every phase of the students' medical progress and it was

take office at the termination of the annual meeting at which they were elected.

Article VI

Trustees

The Board of Trustees shall consist of five members elected by the House of Delegates in accordance with the By-Laws. The President, the Secretary and the Treasurer shall sit with the Board of Trustees with voice but without vote.

Article VII

Board of Censors

There shall be a Board of Censors consisting of the President and Secretary of the Society and the eight Presidents of District Branches, as provided in the By-Laws.

Article VIII

Meetings

There shall be an annual meeting of the Society and of the House of Delegates to be held at a time and place designated by the House of Delegates.

Article IX

Funds

Funds shall be raised by an annual per capita assessment on each component County Society at a uniform per capita rate throughout the State. Funds may also be raised in any other manner approved by the House of Delegates or by the Council when the said House of Delegates shall not be in session.

The approval of the Council and of the Board of Trustees shall be necessary for the expenditure of any funds of the Society.

Article X

Referendum

At any meeting of the House of Delegates a majority of the members present may order a referendum vote of the Society on any question consistent with the Constitution and By-Laws and in accordance with such regulations respecting the submission of the question as the House of Delegates may prescribe. The members shall vote thereon by mail. The polls shall be closed at the expiration of fifteen days after the mailing of the question, and if the members voting shall comprise a majority of all the active members of the Society, a majority of such vote shall determine the question and be binding on the Society and the House of Delegates. The Council may, in a similar manner, order a referendum to the House of Delegates.

Article XI

District Branches

Sec. 1 The membership of the Society

shall be divided into eight District Branches as follows:

The First District Branch shall comprise the members of the Medical Societies of the Counties of New York, Bronx, Westchester, Rockland, Dutchess, Putnam, Orange, and Richmond.

The Second District Branch shall comprise the members of the Medical Societies of the Counties of Kings, Queens, Nassau and Suffolk.

The Third District Branch shall comprise the members of the Medical Societies of the Counties of Albany, Rensselaer, Schoharie, Greene, Columbia, Ulster and Sullivan.

The Fourth District Branch shall comprise the members of Medical Societies of the Counties of St. Lawrence, Franklin, Clinton, Essex, Hamilton, Fulton, Montgomery, Schenectady, Saratoga, Warren and Washington.

The Fifth District Branch shall comprise the members of the Medical Societies of the Counties of Onondaga, Oneida, Herkimer, Oswego, Lewis, Madison, and Jefferson.

The Sixth District Branch shall comprise the members of the Medical Societies of the Counties of Otsego, Delaware, Chenango, Cortland, Tompkins, Schuyler, Chemung, Tioga and Broome.

The Seventh District Branch shall comprise the members of the Medical Societies of the Counties of Monroe, Wayne, Cayuga, Seneca, Yates, Ontario, Steuben, and Livingston.

The Eighth District Branch shall comprise the members of the Medical Societies of the Counties of Erie, Niagara, Orleans, Genesee, Wyoming, Allegany, Cattaraugus, and Chautauqua.

Sec. 2. Each District Branch may adopt a constitution and by-laws for its government and may amend the same, but before becoming effective they shall be approved by the Council. They shall be consistent with the Constitution and By-Laws of this Society.

Sec. 3. Changes in the number or membership of these District Branches may be made by a two-thirds vote of the House of Delegates at any annual meeting.

Article XII

County Societies

The terms County Medical Society or component County Medical Society shall include all County Medical Societies now in affiliation with this Society or which may hereafter be organized and chartered by the House of Delegates. There shall be but one County Medical Society in each County affiliated with this Society. If there should be an insufficient number of physicians in any of the Counties of this State to form themselves into a component

CONSTITUTION AND BY-LAWS

For convenience of the members and for the final official record, the various Articles, Chapters and their Sections of the Constitution and By-laws as revised by the House of Delegates at its 1937 meeting are here grouped in serial order as they will appear later in pamphlet form

Certain errors in preparation of copy and in proofreading occurred in the printed minutes, Section 37, in the July 15, 1937, issue of the JOURNAL. These have been corrected here. There were two main errors. One came from failure to change the name "Council of Trustees" as in the original submitted revision, to "Council" or "Board of Trustees" as the case might require. Such changes were necessary in Chapter II, Section 8 of By-laws on page 1316, Chapter IX, Section 1, on page 1330, Chap-

ters X, XI, XII, on page 1331, Chapter XV, Section 1, on page 1332, Chapter XV, Section 6, on page 1333, Chapter XVI, Sections 2 and 5, on page 1334. The House had directed this change by motion as recorded on page 1310.

The other error was in Chapter VIII, Section 1 (b). The term "Director of Activities" should have been "General Manager," in keeping with paragraph (a).

For the sake of the record, attention is called officially to a typographical error in the Minutes as printed in the July 1, 1937 issue, page 1249, Section 83. The Delegates to the A.M.A. were elected for the years 1938-9 (instead of 1937-8 as printed).

SAMUEL J. KOPETZKY, Speaker

PETER IRVING, Secretary

Constitution

Article I

Name and Purposes

The name and title of the Society shall be the Medical Society of the State of New York. The purposes of the Society shall be to federate and bring into one compact organization the medical profession of the State of New York, to extend medical knowledge and advance medical science, to elevate the standard of medical education, to secure the enactment and enforcement of just medical and public health laws, to promote friendly intercourse among physicians, to safeguard the professional and economic integrity of its members and to establish and maintain them in appropriate and equitable relationship with the public, with government and with all agencies working in the fields of health and welfare, and to enlighten and direct public opinion in regard to the problems of medicine and health for the best interests of the people of the State.

Article II

Membership

The membership in this Society shall be divided into three classes: (a) Active, (b) Retired, (c) Honorary.

Article III

House of Delegates

There shall be a House of Delegates which shall be the legislative body of the Society and shall be charged with the general management, superintendence, and control of the Society and its affairs and shall have such general powers as may necessarily be incident thereto, except as otherwise specifically pro-

vided by the Constitution and By-Laws. It shall pass upon the credentials and qualifications of delegates and shall decide who are entitled to be members of the House of Delegates. It shall have authority and power to suspend or otherwise discipline its own members, District Branches, component County Medical Societies or any member of the Society charged with special duties for and under authority of the State Society. It shall provide for a division of the scientific work of the Society into appropriate sections, for the organization of the District Branches, for rules and regulations for its own government and for the administration of the affairs of the Society. When the House of Delegates is not in session, the Council shall exercise all the rights and duties of the House of Delegates that are not inconsistent with the Constitution and By-Laws of the Society. (See By-Laws)

Article IV

Council

There shall be a Council composed of the President, the President-Elect, the immediate Past-President, the Secretary, the Treasurer, the Speaker, and nine other members elected by the House of Delegates.

Article V

Officers

The officers of the Society shall be a President, a President-Elect who shall serve as first Vice-President, a second Vice-President, a Secretary, an Assistant Secretary, a Treasurer, an Assistant Treasurer, a Speaker, and a Vice-Speaker of the House of Delegates. They shall

New York as may hereafter be elected All nominations for honorary membership must be endorsed by three members of the Society and forwarded to the Secretary for presentation to the House of Delegates, which by a two-thirds vote of the House of Delegates present and voting shall be declared elected honorary members of this Society Honorary members shall be entitled only to the privilege of attending and addressing the meetings of the Society

Chapter II House of Delegates

Sec. 1 The House of Delegates shall be composed of (a) Delegates elected by the component County Medical Societies, (b) Officers of the Society and other members of the Council and of the Board of Trustees, and (c) the Presidents of the District Branches sitting as District Delegates Past Presidents of the Society shall be life members of the House of Delegates Each component County Society shall be entitled to elect as many delegates as there shall be State Assembly Districts in such County at the time of the election, but each component County Medical Society shall be entitled to elect at least one delegate A component Society representing by its name more than one County shall be entitled to as many delegates as there are Assembly Districts in the Counties named in the title of such Society

Sec. 2 A delegate to this Society shall not be considered in good standing or entitled to vote in the House of Delegates if the component County Medical Society by which he was elected is in default of the payment of any dues or assessments imposed by the House of Delegates, and said County Society has been duly notified of such default, or if such component County Medical Society shall at the time be under sentence of suspension imposed by the House of Delegates, or if such delegate is not in good standing in this Society, or in the component County Medical Society to which he belongs The term of a delegate elected by a County Medical Society shall begin at the first annual meeting of the House of Delegates subsequent to his election.

Sec. 3 The annual meeting of the House of Delegates shall be held on the day before the annual meeting of the Society The sessions of the House of Delegates may be adjourned from time to time as may be necessary

Sec. 4 A quorum shall consist of sixty duly elected or constituted members of the House of Delegates

Sec. 5 The House of Delegates shall hear and finally determine all appeals taken from decisions of the Board of Censors

Sec 6 The House of Delegates shall provide for the issue of charters to County Societies in affiliation with this Society

Sec 7 The House of Delegates shall have authority to appoint special committees from among members of this Society

Sec 8 The following shall be the order of business at the sessions of the House of Delegates

- 1 Calling the meeting to order
- 2 Report of Reference Committee on Credentials
- 3 Roll call by the Secretary
- 4 Reading the minutes of the previous meeting
- 5 Report of the President
- 6 Address by the President-Elect
- 7 Report of the Board of Censors
- 8 Report of the Council
- 9 Report of the Secretary
- 10 Report of the Treasurer
- 11 Report of the Board of Trustees
- 12 Reports of District Branches by District Delegates
- 13 Reports of Special Committees
- 14 Reports of Reference Committees
- 15 Unfinished Business
- 16 New Business
- 17 Adjournment

Chapter III Election of Officers, Councillors, Trustees and Delegates

Sec. 1 The Officers, members of the Council and of the Board of Trustees of the Society, and the Delegates to the American Medical Association shall be elected as the first business of the second day's session of the annual meeting of the House of Delegates No member of the Society who is in arrears for county dues or State Society per capita assessment shall be eligible for any office or entitled to vote for any officer, member of the Council, trustee or delegate

Sec. 2 The President, the President-Elect, who shall serve as first Vice-President, the second Vice-President, the Secretary, the Assistant Secretary, the Treasurer, the Assistant Treasurer, the Speaker and the Vice-Speaker of the House of Delegates shall be elected for one year or until their successors have been duly chosen.

Three members of the Council shall be elected annually for a term of three years, except in 1937 when three shall be elected for three years, three for two years and three for one year In the event of a vacancy a Councillor shall be elected for the unexpired term.

Sec 3 One trustee shall be elected annually for a term of five years In the event of a vacancy, a trustee shall be elected for the unexpired term

County Medical Society, such physicians may become members of the component County Medical Society of an adjoining County when eligible by the Constitution and By-Laws of such County Society

Article XIII Amendments

Amendments to this Constitution, except such as are obligatory by law, shall be made only at an annual meeting of the House of

Delegates. Notice of the proposed amendment shall be given at a previous annual meeting of the House of Delegates, and before the same can be acted upon, it shall be published at least once and at least one month before the annual meeting in the official publication of the Society.

A two-thirds vote of the members of the House of Delegates present and voting shall be necessary for adoption.

Amendments made necessary by law shall be made either by the Council or House of Delegates whenever such necessity exists.

By-Laws

Chapter I Membership

Sec. 1 The active members shall be all active members in good standing of the component County Medical Societies. A copy of the roster of such members, certified to be correct by the Secretary of such County Society shall be evidence of the right of the members whose names appear therein to membership in this Society. No member who has been dropped from the roll of a component County Society by reason of failure to pay dues shall be accepted by another Society except by regular transfer after reinstatement in the original Society.

Sec. 2 The term "good standing" is hereby defined as: (a) A member is in good standing when his dues to his County Society and the assessment of the State Society have been paid when they are due and payable. (b) A member whose dues and assessments are unpaid after May 31 of any current year, is not in good standing. He is in arrears for dues. He has lost his right to malpractice defense by counsel of the Medical Society of the State of New York for any acts upon which suit may be predicated during the period of his arrearage. This last is not recoverable, even when he becomes reinstated. Immediately upon payment of dues during the current year, his right to malpractice defense by counsel of the Medical Society of the State of New York shall be restored from that date. (c) A member whose dues and assessments are unpaid after December 31 of any current year shall automatically be dropped from the rolls of membership of both County and State Societies, without notice to such member by his County Medical Society or the Medical Society of the State of New York, or without further action on the part of either County or State Society, and upon such date, he shall automatically cease to be a member of both County and State Societies.

Sec. 3 Any member expelled from his component County Society or suspended from its rights and privileges, shall likewise be expelled

or suspended for the same period from this Society. The right of appeal to this Society shall not be impaired, nor shall such appeal prevent the carrying out of the judgment of the County Society pending such appeal. Members not in good standing or ceasing to be members of their County Society, shall *ipso facto* have the same status in this Society. Suspension or expulsion shall terminate malpractice defense.

Sec. 4 A member of one County Society shall not be permitted to transfer to membership in another County Society until he has established a legal residence or has his principal office in the County to which he desires transfer. The question of legal residence or principal office shall be verified by the Board of Censors of the County Medical Society to which the member desires transfer.

Sec. 5 Any member convicted in a court of law of a crime evincing moral turpitude shall thereupon cease to be a member of this society.

Sec. 6 A member in good standing in his component County Medical Society, reaching seventy years of age or if permanently disabled may *ipso facto* have the privilege of applying for retired membership in the State Society. All such applications shall be signed by the President and the Secretary of the County Society of the applicant and then sent to the Secretary of this Society for presentation to the House of Delegates for approval. An active member desiring to become a retired member shall apply for such membership to the component County Society of which he is a member. Such applications shall be governed by the Constitution and By-Laws of the Component County Society relative to active membership. Retired members shall not be subject to assessment, but shall be accorded all the rights and privileges of active membership except voting and holding office.

Sec. 7 The honorary members of this Society shall be all persons now on the roster as such and in addition such distinguished physicians residing outside of the State of

or commit the Society to any policy unless the same has been expressly approved by the House of Delegates or by the Council

Sec. 9 The duties of the Council shall also include the study and supervision of the following activities

- (a) All Scientific Work presented at each annual meeting
- (b) Scientific Exhibits
- (c) Medical Education.
- (d) Journal Management and Publication
- (e) Medical and related research
- (f) Arrangements for annual meeting
- (g) Preventive Medicine
- (h) Public Health
- (i) Legislation
- (j) Economics
- (k) Workmen's Compensation
- (l) Health and Welfare Departments of State.
- (m) Medical Publicity
- (n) Hospitals, Clinics and Welfare Agencies
- (o) Cooperative relationships with Federal and State Governments, Foundations and other lay groups
- (p) Malpractice defense and Insurance
- (q) Any activities not otherwise provided for

Sec 10 Committees of the Council may include other members of the Society and shall be appointed by the President subject to the approval of the Council. Each committee shall include at least one member of the Council who shall be chairman, except that he need not be chairman for the committee or committees in charge of activities "A", "B" and "F", Chapter IV, Section 9 of the By-Laws. The membership of committees shall not exceed three including the chairman, except the committee or committees in charge of activities "A", "B", "D" and "F", Chapter IV, Section 9 of the By Laws

Sec. 11 The following shall be the order of business at meetings of the Council

- 1 Calling the meeting to order
- 2 Roll call
- 3 Reading of Minutes
- 4 Communications
- 5 Report of the Secretary
- 6 Report of Treasurer
- 7 Reports of Committees
- 8 Unfinished Business
- 9 New Business
- 10 Adjournment

Chapter V Board of Trustees

Sec. 1 At the first meeting of the Board of Trustees immediately upon the close of the annual meeting of the House of Delegates, it

shall organize under the chairmanship of the senior member and fix the time and place of its regular meetings. The Board of Trustees shall meet at least bi-monthly. Any two members of the Board of Trustees may require the Chairman to call a special meeting at the office of the State Society for such time as shall be designated by them in writing and of which the members of the Board shall have at least seven days' notice.

Sec. 2 The Board of Trustees shall have charge of all property including trust funds and shall supervise the financial affairs of the Society and shall invest the surplus from time to time. The budget prepared by the Council shall be submitted to the Board for its approval, and all resolutions or recommendations of the House of Delegates or Council pertaining to expenditures of money must be approved by the Board of Trustees before the same shall become effective. The fiscal year shall begin July 1st and end June 30th of the following year.

Sec 3 All moneys of the Society received by the Board of Trustees, Council or any member or agent thereof, shall be paid to the Treasurer of the Society. The Board of Trustees shall approve the bond of the Treasurer and the Assistant Treasurer, as to amount, form and surety, and shall employ a certified public accountant licensed by the State of New York to audit the accounts of the Treasurer and Secretary and other agents of the Society and present a statement of the same in its annual report to the House of Delegates. The Chairman of the Board of Trustees shall make a report to the House of Delegates of its transactions for the year and of the amount of money belonging to the Society under its control.

Sec 4 Three members of the Board of Trustees shall constitute a quorum.

Sec. 5 The following shall be the order of business at the meeting of the Board of Trustees

- 1 Calling the meeting to order
2. Roll call by the secretary
- 3 Reading of minutes
- 4 Communications
- 5 Reports
- 6 Unfinished business
- 7 New business

Chapter VI Censors

Sec 1 Five Censors shall constitute a quorum.

The President and the Secretary of the Society shall sit as Chairman and Secretary respectively of the Board of Censors but with-

Sec 4 The first order of business on the second day of the session of the House of Delegates of each annual meeting shall be the nominations for officers of the Society and other members of the Council, a member of the Board of Trustees, delegates to the American Medical Association and the appointment of a sufficient number of tellers by the Speaker. After all nominations have been made the Secretary shall cause to be displayed in full sight of the delegates a list of nominees for each office arranged in alphabetical order, and shall also cause to be distributed a sufficient number of blank ballots for the use of the House of Delegates. These ballots shall have printed or stamped thereon the appropriate headings for each office with spaces thereunder in which may be written the name of the candidate or candidates to be voted for.

Sec. 5 All elections for such offices shall be by ballot, each member depositing his ballot on roll call individually. In the event of a single nominee only for any office, a majority vote without ballot shall elect. In case no nominee for an office receives a majority of votes on the first ballot the nominee receiving the lowest number of votes shall be dropped and a new ballot taken for that office. This procedure shall be continued until one of the nominees receives a majority of the votes cast when he shall be declared elected.

Sec. 6 The following method shall govern the election of delegates to the American Medical Association. Nominations shall be made for not less than double the full number of delegates to be elected, and the delegates shall be declared elected in the order of the highest number of votes cast until the allotted number shall have been chosen, a corresponding number in the next highest order of votes cast shall be declared alternate delegates. When the full quota of elected delegates or alternate delegates is not available for attendance at the meeting the President shall appoint and certify a sufficient number to complete the quota.

Sec. 7 The delegates to the American Medical Association shall be elected in the calendar year preceding the meeting of the House of Delegates of the American Medical Association to which they are elected and in accordance with the Constitution and By-Laws of that body for a term of two years. Delegates may be elected to other medical societies or similar bodies as the interests of the Society may require, and credentials shall be issued to all delegates, signed by the President and Secretary.

Chapter IV Council

Sec 1 The Council shall be the Executive and Administrative body of the Society while

the House of Delegates is not in session and shall control all arrangements for the annual meeting. It shall prepare an annual budget for submission to the Board of Trustees. Its resolutions and actions shall be decisive and final except that all resolutions and actions of the Council are subject to review, reconsideration, and action by the House of Delegates. Its actions shall be governed by the Constitution and By-Laws of the Society and the rules and regulations of the House of Delegates. The Council shall have power and authority to employ, discharge, and arrange duties, and with the approval of the Board of Trustees, fix compensation of and for any employee which it may find necessary for conducting the affairs of the Society.

Sec. 2 The Council shall meet at the close of the annual meeting of the House of Delegates. The members of the Council shall hold office until their successors are duly elected and qualified.

Sec 3 It shall meet at regular intervals at times and places that shall be fixed by the Chairman. Any four members of the Council may require the Chairman thereof to call a meeting for such time and place as shall be designated by them in writing. Members must receive at least two days' notice in letter or telegram from the Society's office.

Sec. 4 A quorum shall consist of nine members.

Sec. 5 The Council shall take such action as is necessary to carry out the Constitution and By-Laws and to give full effect to any resolution or vote of the House of Delegates. It shall also have power to legislate as a House of Delegates, when the latter is not in session, on all matters consistent with the Constitution and By-Laws.

Sec 6 The Council shall have power to fill any vacancy which may occur in any elective office not otherwise provided for, until the next meeting of the House of Delegates.

Sec. 7 The Council shall have responsibility for all publications of the Society and their distribution. Any Special Committee of the Society shall report to the Council and shall be subject in all ways to the Council unless otherwise instructed by the House of Delegates. The Council shall advise the legal counsel in actions brought against members for alleged malpractice. With the aid of legal counsel, it shall examine the Constitution and By-Laws of component County Societies and District Branches and all amendments thereto which may be submitted to the Council for approval and shall approve or disapprove of said amendments.

Sec 8 No Board, Commission, or Committee shall inaugurate or initiate any policy

deliver an address at the annual meeting of the Society. He shall perform such other duties as the House of Delegates or the Council shall require.

Sec. 2. The President-Elect shall perform the duties of the President in the absence of the President. In the event of the President's death, resignation, removal, incapacity or refusal to act, the President-Elect shall succeed him.

Sec. 3. The immediate past president shall be a member of the Council.

Sec. 4. The Speaker shall preside at all meetings of the House of Delegates. He shall appoint all parliamentary committees to serve during the meeting of the House of Delegates at least thirty days in advance of the meeting. All resolutions submitted by County Medical Societies and District Branches to be presented to the House of Delegates should be forwarded to the Speaker at least forty-five days in advance of the annual meeting of the House and referred by him to the appropriate Reference Committee, and all resolutions sent in subsequent to forty-five days should be presented to the House and referred to the appropriate Reference Committee.

Sec. 5. The Vice-Speaker shall perform the duties of the Speaker when requested by the Speaker to do so or in case of the absence, death, resignation or refusal of the speaker to act.

Sec. 6. The Secretary shall attend all meetings of the Society, the House of Delegates, the Council, the Board of Trustees, and the Board of Censors, and shall keep minutes of their respective proceedings. These minutes shall be copied from a stenographer's notes with such deletion only as will not modify, alter, or belound the history of the actions of the said bodies. The stenographer's typewritten copy shall be preserved until ordered destroyed by the House of Delegates.

Sec. 7. The Secretary shall be responsible for and have general charge of the Society's offices and the employees therein. He shall be the custodian of the seal of the Society, and of all books of records and papers belonging to the Society, except such as properly belong to the Treasurer, and shall keep an account of and promptly turn over to the Treasurer all funds of the Society which come into his hands. He shall provide for the registration of the members at all sessions of the Society. With the aid and cooperation of the Secretaries of the County Societies, he shall keep a proper register of all the registered physicians of the State by counties. He shall aid the officers of the District Branches in the organization and improvement of the County Societies and the extension of the

power and influence of the Society. He shall conduct the official correspondence, notifying members of meetings, Officers, Councillors, Trustees and Board members of their election and committees of their appointment and duties. He shall affix the seal of the Society to all credentials issued to members of the Society elected by the House of Delegates and to such other papers and documents as may require the same. He shall make an annual report to the House of Delegates. He shall supply each County Society with the necessary blanks for making their annual reports to this Society. Acting in cooperation with the Council, he shall prepare and issue all programs. He shall be a member of the Council. He shall be ex-officio a member of all boards and committees, without vote. He shall record the name and date of admission of each member of the Society.

Sec. 8. The Assistant Secretary shall aid the Secretary in the work of his office and in the absence or disability of the latter, he shall perform the duties of the office until the Secretary resumes the work, or in case of a vacancy, until a successor shall be elected.

Sec. 9. The Treasurer shall keep accurate books of accounts of all moneys of the Society which he may receive, and shall disburse the same when duly authorized, but all checks drawn by the Treasurer upon the funds of the Society shall be countersigned by the Secretary of the Society. He shall collect, on or before the first day of June in each year, from the Treasurer of each component County Society the State per capita assessment. He shall at the expense of the Society give a bond for the faithful performance of his duties, which shall be approved by the Council as to amount, form, and surety. He shall make an annual report to the House of Delegates and monthly reports to the Council. He shall be a member of the Council.

Sec. 10. The Assistant Treasurer shall aid the Treasurer in the work of his office, and in the absence or disability of the latter, he shall perform the duties of the office until the Treasurer resumes the work, or in case of a vacancy until a successor shall be elected. He shall, at the expense of the Society, give a bond for the faithful performance of his duties, which shall be approved by the Council as to the amount, form, and surety. He shall be entitled to all the rights and privileges of the office while acting as Treasurer.

Sec. 11. *Concerning substitutions in office*
The Second Vice-President, the Assistant Secretary, the Assistant Treasurer and the Vice-Speaker shall serve as the First Vice-President, the Secretary, the Treasurer and the Speaker, respectively, whenever these

out vote except that in case of a tie the President, sitting as Chairman of the Board of Censors, shall cast the deciding vote.

The Board of Censors shall meet upon the call of the President. The Secretary shall prepare and submit the report of the Board of Censors to the House of Delegates.

Sec. 2 The Board of Censors shall have jurisdiction to hear and determine all appeals from decisions on discipline of component County Medical Societies or decisions of such societies which may involve the privileges, rights or standing of members, whether in relation to one another or to County Medical Societies or to this Society. Any member of any component County Medical Society feeling aggrieved by the decision of such Society may within three months after such decision appeal to the Board of Censors of this Society from the decision of such component County Medical Society by filing a notice of appeal with the Secretary of this Society, and the Secretary of the component County Society.

Sec. 3 Any applicant for membership in a component County Medical Society who may have been excluded from membership in such Society, may likewise appeal from the action of said Society excluding him. All decisions shall be subject to appeal to the House of Delegates.

Sec. 4 Any notice of appeal shall set forth in writing the name of the appellant, the name of such component County Medical Society and the date and substance of the decision appealed from and shall indicate the ground or grounds upon which each appeal is taken. If the appellant desires to be present in person or by counsel at the hearing of said appeal, the notice of appeal must so state. In that event, the appellant must file with the notice of appeal a bond in the sum of \$50.00 to cover the costs of said appeal. If the appellant fails to appear in person or by counsel upon the hearing of said appeal, he shall forfeit to the Medical Society of the State of New York such share of said bond as represents necessary expenditures incident to convening the Board of Censors for the hearing of said appeal.

Sec. 5 Upon filing a notice of appeal, the appellant and the component County Medical Society shall submit to the Secretary of the Board of Censors all records, minutes, letters, papers, and all written evidence, including a digest of all testimony not stenographically reported relating to the matter. All data so submitted shall be available only to the Censors, and on appeal, to the members of the House of Delegates.

Sec. 6 The Board of Censors shall consider the appeal on the data so submitted to it, and may affirm by a majority vote, modify or

reverse by a two-thirds vote of the Censors present and voting, the decisions so appealed from. If, in its opinion, the taking of further evidence is advisable, the Board of Censors may summon witnesses and proceed to take such evidence in such manner as it may deem proper and render its decision by a two-thirds vote of those present and voting, which decision shall be binding until reversed or modified by the House of Delegates.

Sec. 7 The Board of Censors shall investigate all charges preferred (a) by a member of a component County Society against any component County Medical Society of which he is not a member, and (b) by a component County Medical Society against another such County Medical Society or a member thereof, and the Secretary of the Board of Censors shall submit the report to the House of Delegates for action thereon.

Sec. 8 Any member or component County Society desiring to appeal to the House of Delegates from the decision of the Board of Censors shall within three months after such decision, file with the Secretary of this Society and the Secretary of the component Society a notice of appeal. Such notice of appeal shall set forth in writing the name of the appellant, the name of the component County Society, the date and substance of decision appealed from and the ground or grounds upon which such appeal is taken. The appellant must also state if he desires to be present in person or by counsel.

Sec. 9 Upon the filing of a notice of appeal the appellant and the Secretary of the Board of Censors shall submit to the House of Delegates the decision and all records, minutes, letters, papers, and all written evidence including a digest of all testimony not stenographically reported relating to the matter.

Sec. 10 The House of Delegates shall consider and decide the appeal on the data submitted to it, and may affirm, modify or reverse the decision so appealed from. Such decision of the House of Delegates shall be final and binding.

Chapter VII Duties of Officers

Sec. 1 The President shall preside at all meetings of the Society, the Council and the Censors. He shall be ex-officio member of the Board of Censors and of all committees. He shall appoint all committees not otherwise provided for, subject to the approval of the Council. He shall assign the special branches of work for which the members of the Council shall be responsible, subject to the approval of the Council. He shall also appoint all members of committees of this Council, subject to the approval of the Council. The President shall

gaged upon official business. Members of the Council, of the Board of Trustees and of the Board of Censors, shall be allowed traveling expenses. Members of Committees of the Council, and all special committees of the Society, shall be allowed traveling expenses. There shall be no allowance made for the expenses, traveling or otherwise, for any committee appointed pursuant to Chapter XI of these By-Laws. Proper vouchers must be filed with the Secretary and approved by the Board of Trustees before any of above allowances are made. The delegates to the American Medical Association who have attended each session of the House of Delegates of that Association and who shall have filed with the Secretary evidence of such attendance shall be allowed the actual cost of railroad transportation and Pullman accommodations to the place of meeting and return. The vouchers of such expense shall be approved by the Board of Trustees before payment. Each District Branch shall be entitled to receive a sum not to exceed \$200, exclusive of the work done by the Secretary regarding notices, programs, etc., to defray the expenses of holding the annual meeting of such District Branch, provided a proper statement of such expense shall have been presented to the Secretary and approved by the Board of Trustees. All bills, claims or vouchers herein provided for shall be filed within thirty days after the date of the incurring of such expense. This time may be extended for any cause by the Board of Trustees and such extension shall not exceed ninety days.

Chapter XI

Reference Committees

Sec. 1 At least one month before the meeting of the House of Delegates the Speaker shall appoint and publish in the JOURNAL such Reference Committees as he shall deem expedient for the purposes of the meeting. Immediately after the organization of the House of Delegates he shall formally announce the appointments of the Committees. Only members of the House of Delegates are eligible for appointment on the Reference Committees. Such Committees shall consist of five members, three members constituting a quorum, and shall serve during the meeting for which they are appointed.

Sec. 2 Reports of Officers, Council, Board of Trustees, Board of Censors, and Committees shall be printed at least one month before the meeting of the House of Delegates and sent to the members of the Reference Committee appointed according to Section 1, for their preliminary consideration. All recommendations, resolutions, measures, and propositions presented to the House of Delegates

and which have been duly seconded shall be referred by the Speaker to the appropriate Reference Committees.

Sec. 3 Each Reference Committee shall immediately consider such business as may have been referred to it and shall report promptly to the House.

Chapter XII

Special Committees

Sec. 1 Special Committees may be created by the House of Delegates to perform the special functions for which they are created. They shall be appointed by the officer presiding over the meeting at which the committee is authorized if such committee is to conclude its work during said meeting of the House of Delegates. The President shall appoint all other committees subject to the approval of the Council unless otherwise ordered by the House of Delegates.

Sec. 2 A Special Committee on Prize Essays consisting of three members, including the Chairman, shall be appointed by the President with the approval of the Council. Its duty shall be to receive all essays offered in competition for prizes which may be offered by this Society. The Committee shall make all necessary rules and regulations for the award of prizes subject to the terms of the deeds of gift, and shall report the result at the next annual meeting of the House of Delegates. It shall give notice through the Society's publication or by other methods within thirty days after appointment, of the amount of the prize and when the essays shall be submitted to the Committee.

Sec. 3 Any member of the Society shall be eligible to serve on Special Committees. All members of such committees, who are not members of the House of Delegates, shall have the right to present their reports in person to the House of Delegates and to participate in the debate thereon, but shall not have the right to vote.

Chapter XIII

Sections

Sec. 1 The Scientific Sections designated by the House of Delegates shall each organize by the election of a Chairman and Secretary. The Chairman shall be elected annually, the Secretary for such term as the Section may deem fit.

Sec. 2 The officers of the various Sections shall prepare programs for their Sections under the direction and subject to the approval of the Council.

Sec. 3 The election of officers of Sections shall be the first order of business of the first session of the second day of each annual

senior officers are incapacitated for service by injury, ill health of themselves or families, imperative professional duties, or by other mandatory absences. This shall be construed so as to include duty at or during meetings of the Council and Board of Trustees, as well as the other official duties designated for the senior officer. The senior officer shall promptly notify the junior officer of his incapacity and request his attention to said duties.

Sec. 12 Each President of a District Branch shall visit the County Societies of his district at least once a year and make a careful inquiry of the condition of the profession in each county in his district and shall report thereon to the House of Delegates.

Chapter VIII Direction of Activities

Sec. 1 (a) An officer to be known as the General Manager shall be employed by the Society. He shall be a member of the Medical Society of the State of New York, who has established a reputation for executive ability, and who will give his full time and undivided attention to the affairs of the Society. He shall have been in actual practice for at least ten years or shall have qualifications which in the opinion of the Council are equivalent to the same.

(b) The duties of the General Manager shall be as follows. He shall have general management of the executive details of the Society's business, subject to the Council, he shall be the coordinator of all activities of the Society, he shall act as Secretary of the House of Delegates, of the Council, of the Board of Censors and of the Board of Trustees. He shall be eligible for election as Secretary of this Society.

Sec. 2 An officer to be known as the Executive Officer shall be employed by the Society. He shall assist the General Manager. He shall be a member of the Medical Society of the State of New York, who has established a reputation for executive ability and who will give his full time and undivided attention to the affairs of the Society, subject to the direction of the Council. He shall have been in actual practice for at least seven years, or shall have qualifications which in the opinion of the council are equivalent to the same.

Chapter IX Meetings

Sec. 1 The notices of the annual and special meetings of the Medical Society of the State of New York, and its House of Delegates, and of regular meetings of the Council, of the Board of Trustees and the Board of Censors, shall state the date, place and hour and shall be

mailed in securely postpaid wrapper to each member of the body holding such meeting at least seven days before said meeting. The affidavit of mailing by the Secretary of the Society to the last recorded address of the member shall be deemed sufficient proof of the service upon each and every member for any and all purposes.

Sec. 2 Each member in attendance at the annual or special meeting of the Society shall enter his name and the name of the component County Medical Society to which he belongs in a register to be kept by the Secretary of the Society for that purpose. No member shall take part in any of the proceedings of such meeting until he shall have complied herewith.

Sec. 3 All members in good standing so registered may attend and participate in the proceedings and discussions of the general meetings of the Society and of the Sections.

Sec. 4 The following shall be the order of business at all general meetings of the Society:

- 1 Calling the Society to order
- 2 Address of welcome by the Chairman of the Committee on Arrangements
- 3 Reading the minutes of the last meeting
- 4 Miscellaneous business
- 5 President's address
- 6 Special addresses
- 7 Reading and discussion of papers

Sec. 5 Special meetings of the Society shall be called by the President upon the request in writing of two hundred and fifty members from the membership of at least ten component County Societies, and in case of the failure, inability or refusal of the President to act, such meeting may be called by a notice thereof subscribed by two hundred and fifty members from the membership of at least ten component County Societies.

Sec. 6 Special meetings of the House of Delegates shall be called by the Speaker upon the request in writing of sixty delegates, or at request of the Council, and in case of the failure, inability or refusal of the Speaker to act, such meetings may be called by a notice thereof subscribed by sixty delegates.

Chapter X Expenses

Sec. 1 Allowances for expenses incurred in the actual performance of official duties by officers, members of the Council, the Board of Trustees, of the Board of Censors and committees, and delegates to the American Medical Association shall be made in conformity with the following conditions. The President shall be allowed a per diem and expenses when engaged upon official business. All other officers shall be allowed traveling expenses when en-

gaged upon official business. Members of the Council, of the Board of Trustees and of the Board of Censors, shall be allowed traveling expenses. Members of Committees of the Council, and all special committees of the Society, shall be allowed traveling expenses. There shall be no allowance made for the expenses, traveling or otherwise, for any committee appointed pursuant to Chapter XI of these By-Laws. Proper vouchers must be filed with the Secretary and approved by the Board of Trustees before any of above allowances are made. The delegates to the American Medical Association who have attended each session of the House of Delegates of that Association and who shall have filed with the Secretary evidence of such attendance shall be allowed the actual cost of railroad transportation and Pullman accommodations to the place of meeting and return. The vouchers of such expense shall be approved by the Board of Trustees before payment. Each District Branch shall be entitled to receive a sum not to exceed \$200, exclusive of the work done by the Secretary regarding notices, programs, etc., to defray the expenses of holding the annual meeting of such District Branch, provided a proper statement of such expense shall have been presented to the Secretary and approved by the Board of Trustees. All bills, claims or vouchers hereon provided for shall be filed within thirty days after the date of the incurring of such expense. This time may be extended for any cause by the Board of Trustees and such extension shall not exceed ninety days.

Chapter XI

Reference Committees

Sec. 1 At least one month before the meeting of the House of Delegates the Speaker shall appoint and publish in the JOURNAL such Reference Committees as he shall deem expedient for the purposes of the meeting. Immediately after the organization of the House of Delegates he shall formally announce the appointments of the Committees. Only members of the House of Delegates are eligible for appointment on the Reference Committees. Such Committees shall consist of five members, three members constituting a quorum, and shall serve during the meeting for which they are appointed.

Sec. 2 Reports of Officers, Council, Board of Trustees, Board of Censors, and Committees shall be printed at least one month before the meeting of the House of Delegates and sent to the members of the Reference Committee appointed according to Section 1, for their preliminary consideration. All recommendations, resolutions, measures, and propositions presented to the House of Delegates

and which have been duly seconded shall be referred by the Speaker to the appropriate Reference Committees.

Sec. 3 Each Reference Committee shall immediately consider such business as may have been referred to it and shall report promptly to the House.

Chapter XII

Special Committees

Sec. 1 Special Committees may be created by the House of Delegates to perform the special functions for which they are created. They shall be appointed by the officer presiding over the meeting at which the committee is authorized, if such committee is to conclude its work during said meeting of the House of Delegates. The President shall appoint all other committees subject to the approval of the Council unless otherwise ordered by the House of Delegates.

Sec. 2 A Special Committee on Prize Essays consisting of three members, including the Chairman, shall be appointed by the President with the approval of the Council. Its duty shall be to receive all essays offered in competition for prizes which may be offered by this Society. The Committee shall make all necessary rules and regulations for the award of prizes subject to the terms of the deeds of gift, and shall report the result at the next annual meeting of the House of Delegates. It shall give notice through the Society's publication or by other methods within thirty days after appointment, of the amount of the prize and when the essays shall be submitted to the Committee.

Sec. 3 Any member of the Society shall be eligible to serve on Special Committees. All members of such committees, who are not members of the House of Delegates, shall have the right to present their reports in person to the House of Delegates and to participate in the debate thereon, but shall not have the right to vote.

Chapter XIII

Sections

Sec. 1 The Scientific Sections designated by the House of Delegates shall each organize by the election of a Chairman and Secretary. The Chairman shall be elected annually, the Secretary for such term as the Section may deem fit.

Sec. 2 The officers of the various Sections shall prepare programs for their Sections under the direction and subject to the approval of the Council.

Sec. 3 The election of officers of Sections shall be the first order of business of the first session of the second day of each annual

meeting To participate in the election of any Section, a member must be registered with such Section and must have recorded his name and address in the Section registry

Sec 4 Each Section shall hold its meetings at such times as designated by the Council

Chapter XIV District Branches

Sec 1 Each District Branch shall elect a President for two years, who shall be a District Delegate of the House of Delegates during his term in said office.

Sec 2 Each District Branch shall elect such officers as are provided for in its By-Laws, who shall attend the business meetings of the Branch

Chapter XV Component County Medical Societies

Sec. 1 (a) Eligibility for membership in County Medical Societies shall be determined by the Boards of Censors or Comitae Minorae of the County Medical Societies. Except by approval of the Council of the Medical Society of the State of New York, no physician shall be an active member in a County Medical Society other than that of the county in which he maintains legal residence or has his principal office.

(b) In order that a member desiring to correct his membership pursuant to the terms of this section shall have an opportunity to do so without impairing his status as an active member, a period of six months from the date of the adoption of this section must elapse before the Board of Censors or the Comitae Minorae of any County Medical Society shall have the right to declare a member ineligible by reason of the fact that he neither maintains a legal residence nor has his principal office in the jurisdiction of the County Medical Society of which he is then a member

Sec. 2 Whenever an active member in good standing in any component County Medical Society removes to another County in this State, his name upon his request, shall be transferred to the roster of the component County Medical Society of the County to which he removes, without cost to him, provided that he files a certificate with the Secretary signed by the President and Secretary of the component Society from which he removes as to his good standing in such Society. No member, however, shall be an active member of more than one component County Society, nor shall any component County Society accept a physician residing in another County in any other way than in accordance with the law governing transfers

When a member in good standing ceases to reside and practice in the State of New York

he shall *ipso facto* cease to be an active member of the Society and of his component County Medical Society at the end of the current year. His status shall be deemed that of a resigned member and all rights and title to any share in the privileges and property of the Society, the District Branch, or County Society, shall be deemed to have been forfeited by such action.

The dues of any member of the Medical Society of the State of New York may be remitted for the current year on account of illness when the request is made by the member's component County Medical Society

Sec 3 At its annual meeting each component County Medical Society shall elect a delegate or delegates to represent it in the House of Delegates of this Society in accordance with the Constitution and By-Laws of this Society

Sec. 4 The Secretary of each component County Medical Society shall keep a roster of its members in which shall appear the full name of each of said physicians, the date of his admission to such society, his residence, and the date when his license to practice medicine in this State was granted. He shall note any changes in said roster by reason of removal, death or change of name, revocation of license or other disqualification

He shall forward said roster and information together with the names and places of residence of each of the officers of said society and the names and residence of each delegate of the House of Delegates of said society to the Secretary of this Society sixty days before the date of its annual meeting

Sec. 5 The Treasurer of each component County Medical Society shall forward to the Treasurer of this Society the amount of the State per capita assessment on or before the first day of June of each year

Sec 6 Each component County Medical Society shall adopt a Constitution and By-Laws for the regulation of its affairs and may amend the same provided they shall be first approved by the Council before becoming effective. The Constitution and By-Laws of component County Societies must not be in conflict with the Constitution and By-Laws of this Society

Chapter XVI Miscellaneous

Sec. 1 No address or paper before the Society, except those of the President and orators, shall occupy more than twenty minutes in its delivery, and no member shall speak upon any question before the House of Delegates for longer than five minutes nor more than once on any subject, except by the consent of a majority vote.

Sec. 2 All papers read before the Society by its members shall become the property of the Society. Permission may be given, however, by the Council or House of Delegates to publish such paper in advance of its appearance in the *NEW YORK STATE JOURNAL OF MEDICINE*.

Sec. 3 Any distinguished physician of a foreign country or a physician not a resident of this State, who is a member of his own State Association, may become a guest during any annual session upon the invitation of the President or officers of the Society, and may be accorded the privilege of participating in all the scientific work of the session.

Sec. 4 The rules contained in Robert's Rules of Order shall govern the Society and the House of Delegates in all cases in which they are not inconsistent or in conflict with the Constitution and By-Laws of the Society or the standing or special rules of the House of Delegates.

Sec. 5 Written charges may be preferred against any Officers, Councillors, Trustees, and members of Boards and Special Committees of the Society, for malfeasance or nonfeasance in office, by any member and transmitted to the President. The President shall order a trial upon said charges by the Council, or a Committee thereof, and in the event of such trial the accused shall be given at least ten days' notice of such charges and have full opportunity to defend the same, but no such officer or member of the committee shall be removed or otherwise disciplined except by a two-thirds vote of the Council. In case any such officer, or trustee, or member of a board or committee shall be removed, he may appeal from the decision of the said Council to the House of

Delegates, but, pending the determination of such appeal, he shall not exercise the functions of his office.

Sec. 6 Sections of the By-Laws which refer to the order of business and to reference committees may be suspended by a two-thirds vote of the House of Delegates.

Chapter XVII

Sec. 1 The seal of the Society shall be as follows

Chapter XVIII

Amendments

Sec. 1 Amendments to these By-Laws, except such as are obligatory by law, shall be made only at an annual meeting of the House of Delegates.

Sec. 2 Notice of the proposed amendment shall be given at a previous annual meeting of the House of Delegates, and before the same can be acted upon it shall be published once before the annual meeting in the official bulletin or journal of the Society.

Sec. 3 The affirmative vote of two-thirds of the House of Delegates present and voting shall be necessary for adoption.

Sec. 4 Amendments made necessary by law shall be made either by the Council or House of Delegates whenever such necessity exists.

INTER-STATE POSTGRADUATE MEDICAL ASSOCIATION

The International Assembly of the Inter-State Postgraduate Medical Association of North America, under the presidency of Dr. John F. Erdmann of New York City, will be held in the beautiful new public auditorium of St. Louis, Mo., October 18-22, with pre-assembly clinics on October 16 and post-assembly clinics October 23 in the hospitals of St. Louis.

The aim of the program committee, with Dr. George Crile as chairman, is to provide for the medical profession of North America an intensive postgraduate course covering the various branches of medical science. The program has been carefully arranged to meet the demands of the gen-

eral practitioner, as well as the specialist. Extreme care has been given in the selection of the contributors and the subjects of their contributions.

The St. Louis Medical Society will be host to the Assembly and has arranged an excellent list of committees who will function throughout the Assembly.

A most hearty invitation is extended to all members of the profession who are in good standing in their State or Provincial Societies to be present. A registration fee of \$5.00 will admit each member to all the scientific and clinical sessions.

For further information, write Dr. W. B. Peck, Managing-Director, Freeport, Ill.

Public Health News

Tuberculin Testing with P P D.

The development of P P D, which is a standardized nontensitizing tuberculin, with instructions for uniform performance and interpretation, made it possible for the National Tuberculosis Association to make a more reliable and complete survey of the prevalence of tuberculosis infection in the United States than heretofore. The results of group testing with MA-100, the first standardized tuberculin to be recommended for trial by the Committee on Medical Research of the National Tuberculosis Association, were published early in 1936 and are still valid as a measure of tuberculous infection in groups studied for the first time. However, because of the possibility of MA-100 itself sensitizing children, and in view of the advisability of keeping the results of tuberculin testing aligned with those obtained with Old Tuberculin in the past, the National Tuberculosis Association replaced MA-100 with P P D in June, 1934, and began a new study of infection in the United States. The significant findings of that study are presented in this report.

During the two-year period following June 1934, the National Tuberculosis Association offered P P D for sale at a reduced price for group testing with the understanding that reports would be returned for statistical analysis. By this means, data were obtained for 85,709 first- and second-strength tests among 56,688 individuals in thirty states and the District of Columbia and the group tests were summarized with the result that the individual differences of single groups were minimized. The percentage of positive reactors among the 56,688 persons tested with first- and second-strength P P D was found to be 36.4. However, a more representative index of tuberculous infection in the United States was approached by adjusting the infection rates for age, color, nativity, and parentage according to the distribution of the population in the United States at the time of the last census in 1930. In this way, added importance was given to the high infection rates found among the adults and persons of foreign extraction in the groups tested, and the percentage of positive reactors was increased to 47.0 per cent.

Of the 55,688 persons included in this survey, 3,071 were tested with second-strength tuberculin only. The remaining 53,617 persons were tested with first-strength tuberculin and only 29,021, or 75 per cent of the 38,829 negative reactors, were retested with second-strength tuberculin. Positive reactions resulted from 27.6 per cent of the first-strength test and 16.9 per cent of the second-strength tests that followed negative reactions to first-strength tuberculin. However, there were 9,808 negative reactors to first-strength tuberculin who failed to receive second injections

of second-strength tuberculin. Assuming that these would have shown positive reactions to second-strength tuberculin in the same proportion as those who did receive second-strength tests, there are at least 1,500 undiscovered positive reactors because of the failure to complete tests with second-strength tuberculin.

Type of group. More than eighteen per cent of those tested with P P D were high-school students, seventeen per cent were college students, twelve per cent were elementary school pupils, and thirteen per cent came from clinics. Another thirteen per cent were Indians, and less than one per cent were teachers, nurses, and doctors. The remaining twenty-seven per cent came from miscellaneous or unclassified groups. Excluding the Indians reported, the highest infection rate was found among the 7,106 persons tested in clinic groups, with 53.2 per cent showing positive reactions to either first- or second-strength P P D. The lowest percentage of positive reactors, 18.5, was found among the 6,622 elementary school children in the groups tested.

Geographic areas. With the exception of the resort area, the states along the Eastern coast showed the greatest evidence of tuberculous infection, whereas the lowest percentage of positive reactors was found among the groups in the central states. The number of persons tested in each geographical area was not large enough to establish conclusive evidence concerning the prevalence of tuberculous infection in each section, but it is interesting to note that the results of this study are in agreement with those found among students tested in colleges in various sections of the United States.

Reprinted by permission of *Tuberculosis Abstracts*, July 1937

Urban and rural. Tuberculin tests among 32,477 individuals were reported either

typically urban or typically rural Of the 22,688 persons classified as urban residents, that is, living in places with a population of over 2,500, 33.6 per cent were found to be positive reactors to either first- or second-strength P P D There were 9,789 individuals included in the study of rural groups, of which 21.4 per cent evidenced tuberculous infection.

Age The reports included in this study indicated that there were fewer positive reactors proportionately among the children six years of age than there were at any other year of life. Following the sixth year of life, the percentage of positive reactors increased with age at an average rate of over one per cent for every year of life up to the age of twenty Adults twenty years of age and over included in the groups tested evidenced thirty-four per cent more tuberculous infection than the boys and girls reported under twenty years of age.

Sex Approximately the same number of males and females were reported to have had tuberculin tests with P P D The males showed a slightly higher percentage of positive reactors than did the females, the adjusted rate for males being 48.3 and that for females 45.9 per cent. There was a larger proportion of male than female positive reactors to P P D at almost every age group.

Contact and non-contact Almost fifteen per cent of the total number tested were reported to have had some definite contact with tuberculosis The percentage of positive reactors among them was 54.2 whereas only 33.3 per cent of those for whom no history of contact with tuberculosis was reported showed evidence of tuberculous infection. The infection rate indicated for contacts under five years of age was three times that found for non-contacts in the same age-group, but the proportion of positive reactors increased with age generally at a more rapid rate among the non-contacts than among the contacts.

Color and race The Negroes and Indians seemed to be more sensitive to P P D than the white persons tested. Of the white positive reactors in the groups tested with

second-strength tuberculin following negative reactions to test with first-strength tuberculin, sixty-eight per cent were detected with first-strength tuberculin, compared with seventy-five per cent for the Negroes and eighty-nine per cent for the Indians White persons comprised seventy-four per cent of the entire number included in the study, and the percentage of positive reactors among them adjusted for age, nativity and parentage was 46.5 The Negroes tested showed only one per cent more positive reactions proportionately than did the whites, the infection rate for the Negroes adjusted for age being 47.8 per cent. The nonadjusted rate for whites was fifteen per cent lower than that found for Negroes, but it was thought that the adjusted rates represented more closely the prevalence of infection in the general population The percentage of positive reactors found among the 7,159 Indians tuberculin tested was 72.4, an infection rate over twenty-five per cent higher than the adjusted rate found for the combined groups of all ages, colors and races included in the study More than half of the Indians tested were found to be positive reactors at every age after the seventh year of life, and nine out of every ten tests at twenty years of age and over showed evidence of tuberculous infection.

Nativity and parentage Nativity and parentage seemed to be significant factors in tuberculous infection among the white persons tested Of the 31,318 native-born Americans of native parentage, 27.6 per cent evidenced tuberculous infection, whereas 38.4 per cent of the 6,674 native-born of foreign stock and 61.2 per cent of the 814 foreign-born responded with positive reactions to P P D.

Unfortunately, the number reported for each country was too small for valid conclusions, but a notably higher infection rate was indicated for the foreign-born from the European countries than for those removed from the same country by one generation.

Medical News

Allegany County

WELLSVILLE PHYSICIANS have announced a change in schedule for the months of July and August, whereby six of the doctors will close their offices Saturday nights while one doctor will be available for emergency cases. The same procedure will be followed each Thursday afternoon and evening.

Delaware County

DR JOSEPH LAWRENCE, Executive Officer of the State Society, addressed the quarterly meeting of the Delaware County Medical Society at Downsview on June 15.

Herkimer County

DR J J McEVILLY won the Herkimer County medical golf championship at the Mohawk Valley Country Club on June 30.

Doctor McEvilly turned in the lowest net tally and won the president's prize. Dr G A Burgin, Little Falls, was winner of the vice-president's handicap prize and Dr H J Sheffield, Frankfort, won the blind prize award.

Kings County

THE MEDICAL PROFESSION in Brooklyn will be aided considerably by the proposed merger of the New York and Brooklyn units of the Federation of Jewish Charities, it was predicted at a dinner meeting tendered to more than 300 of the borough's doctors by Nathan S Jonas, president of the Jewish Hospital, held in the Unity Club. The influx of fresh money from the New York division will stimulate hospital and clinic welfare work to the advantage of local doctors, Supreme Court Justice Mitchell May, past president of the Brooklyn Federation, and Lawrence Marx, president of the New York Federation, said.

DR ONSLOW A GORDON, eighty-four, Brooklyn surgeon and former president of the Medical Society of the County of Kings, died after a brief illness at his Summer home at Lake Keoka, in Maine, on July 4. Dr Gordon had practiced in Brooklyn for fifty years, and for forty-eight years was a member of the staff of St. Mary's Hospital. A tribute to his long professional career was paid him four years ago when

more than 100 physicians, clergymen and prominent laymen attended a dinner held in the Montauk Club, Brooklyn, in honor of his golden anniversary as a surgeon.

Madison County

THE MADISON COUNTY Medical Society and Women's Auxiliary held a joint outing Thursday, July 15, at Lake Moraine. A broiled steak supper was served.

New York County

ABOUT FORTY PHYSICIANS in New York County are to be hailed before the State Medical Grievance Committee for disciplinary action in irregularities in connection with fraudulent accident indemnity claims during recent years, it was announced on July 8 at a luncheon conference of the committee, held in the Academy of Medicine. The conference was an adjunct of the annual meeting of the committee, and was presided over by Dr Orrin Sage Wightman, the chairman.

District Attorney William C Dodge, Assistant District Attorney Bernard Botin, head of the Accident Fraud Bureau, which in the last year has broken up several rings of fraudulent accident claims, including lawyers and doctors, were guests of the committee. Others present were Sol Ullman, Assistant State Attorney General, who is legal adviser to the committee, and the members of the committee.

The committee adopted a resolution commending District Attorney Dodge and Assistant District Attorney Botin for the "effective work they have accomplished in the recent accident fraud investigation toward purging the medical profession."

District Attorney Dodge assured the gathering that the bureau would be continued as a permanent branch of the District Attorney's office.

Mr Ullman said the committee already has received papers in disciplinary charges against twenty-eight physicians in New York County which had been developed by Assistant District Attorney Botin in the investigation started last July at the request of the Appellate Division, and bar association papers are being prepared against about ten more, he disclosed.

"These represent the more flagrant of-

fenders," Mr Botein said "Most of them were definitely allied with fraudulent accident claims or workmen's compensation rings"

He added that "their transgressions usually took the form of furnishing medical certificates for non-existent claimants or certifying or testifying to severe injuries in numerous cases after most cursory examinations"

District Attorney Dodge remarked that, in addition to the physicians to whom Mr Ullman had referred, ten physicians already had been convicted in Special Sessions by Assistant District Attorney Botein in fake accident indemnity claims and two more are awaiting trial

He commented, however, that Mr Botein also had uncovered some physicians not allied with any of the fake accident rings but who had furnished fraudulent certificates to patients and friends, when requested. He recommended that the committee and the various medical societies of the State launch immediately "a thorough-going educational and disciplinary campaign to eliminate this practice"

Oneida County

MEMBERS of Oneida County Medical Society gathered at Trenton Falls for their annual outing on July 13

The society voted to name a committee to help examine 4-H boy and girl contestants from the county who are going to the State Fair Such a move was suggested to various county groups recently by the State Medical Society

Dr William Hale, Jr, president, announced that Dr M. D. Graham's 1936 speech as retiring president, and Dr B. P. Allen's of 1933 had been published recently Dr Charles H. Goodrich, president of the State Medical Society praised the public relations council for its education work in the past year, and Dr Joseph Lawrence, executive officer of the state organization, reviewed the cancer and tuberculosis drives and told of plans for the district meeting in Lowville Sept. 2

Ontario County

DR. GEORGE E. WELKER was elected president of the Geneva Academy of Medicine succeeding Dr R. E. Doran at the regular meeting at the Geneva Country Club on June 17 Other officers elected were vice president, Dr S. J. Morabito, treasurer, Dr M. D. Dickinson, Jr, secretary, Dr Philip W. Skinner The new officers will take office

at the next meeting in September Guest speaker was Dr Norris Maslon, director of the Warren County Bacteriological Laboratory at Glens Falls, N. Y. His subject was "The Relationship between the Medical Profession and the County Governing Boards"

Orange County

THE INNOVATION of HOLDING a meeting at which its own members read papers and conducted discussions on scientific subjects was tried with success by Orange County Medical Society when the society met in the dining room of St. Luke's Hospital on June 15

Registered nurses of the county were guests, and Miss Ella Vincent, president, headed a delegation of members of the Alumnae Association of St. Luke's Training School for Nurses, and a group of nurses of Newburgh Health Department attended After the meeting luncheon was served

The scientific program Tuberculosis of the Genito-Urinary Tract, Dr Harold Snyder, discussion by Dr D. R. Gordon, Tumors of the Neck, Dr Ian Macdonald, discussion, Dr E. C. Thompson, Amnesia-Altesia in Labor, Dr David Tolmie, discussion by Dr H. F. Morrison

Oswego County

THE OSWEGO COUNTY Medical Society held a luncheon meeting on July 1 at the Oswego County Sanatorium. Dr Fred Metilde, member of the Monroe County committee on social hygiene, was the principal speaker

Queens County

DR. HAROLD EICHACKER, president-elect of the Queens County Medical Society, whose suit to collect an alleged overpayment of \$209 from the New York Telephone Company was dismissed last June by Justice Harold Crawford in the Municipal Court in Ridgewood, announced on July 17 he had filed notice of appeal

E. F. W. Wildermuth, attorney for Dr Eichacker, said the appeal would be argued in the Appellate Court in October Dr Eichacker in his suit claimed he should have been charged for his telephone at residential rate and had been billed at the business rate.

Rensselaer County

THE ANNUAL OUTING OF THE Rensselaer County Medical Society was held on June

24 The program began at 1 P M with a buffet luncheon followed by golf and softball during the afternoon and a dinner at the club house at 6 30 During the afternoon, a "kickers" handicap golf tournament was held with Dr Robert E Plunkett capturing the first prize, a set of matched irons Dr D Edward Rowan took second prize, a leather golf bag, and Dr Clayton L Gifford won third award, a box of golf balls In the softball game, the "Oldsters" demonstrated fine fitness in defeating the "Youngsters" by 9 to 5 Dr Walter H McShane pitched for the winners, with Dr F S Haverly, catching The battery for the "Youngsters" was Dr Gilbert A Clark, pitch, and Dr Hugh V Foley, catch

Rockland County

DR RUSSELL E BLAISDELL, medical superintendent of the Rockland State Hospital, represented the psychiatrists of the United States as the single delegate to the International Congress of Mental Hygiene in Paris during the week of July 19, as delegate of the American Psychiatric Association. Two other Rockland State Hospital doctors, Dr Hamlin A Starks and Dr Reginald N Taylor, and Mrs Starks also went to the convention

St Lawrence County

DR S W CLOSE presided at the monthly meeting of the St Lawrence County Medical Society at the Country club, in Ogdensburg, on June 24 Dr W H Mulholland, president, was unable to be present.

Following luncheon the matter of having a joint meeting with the County Dental Society was discussed and a committee comprising Drs R L Stacy and M J Stearns were named to take up the matter with the dentists

While the doctors played golf in the afternoon their wives enjoyed bridge in the clubhouse.

Suffolk County

DR. ALBERT E PAYNE, who died on June 21 at the age of sixty-five, was a past president of the Suffolk County Medical Society

Washington County

THE MEDICAL SOCIETY of the County of Washington met on July 6 at the Central School Annex in Fort Ann The program "The Friedman Modification of the Ascheim-Zondek Test for Pregnancy Its

value in differential diagnosis with a practical demonstration of the test."—Dr Harold A Peck

"Report of a Case, Carcinoma of the Lung"—Dr Royal E LaGrange.

"Some Phases of Tuberculosis, with a Differential Diagnosis from Carcinoma of the Lung"—Dr Lyman I Thayer

The October (Annual) Meeting will be held at Hudson Falls

Westchester County

PLANS FOR A NEW HEALTH laboratory, which would make possible periodical examination of all food handlers, dairy workers, domestics, criminals or any who might in any way be germ carriers, were put before the Greenwich Board of Health on June 7 by Dr Albert E Austin, health officer, who presented the plan earlier in the day to a meeting of the Family and Child Welfare Committee of the Greenwich Community Chest and Council

Control of venereal diseases, called by the American Public Health Association the "greatest need of Greenwich today," is one of the main objectives in the program planned in conjunction with the installation of the laboratory Dr Austin said that he would present a preliminary survey of the need for extension of present laboratory facilities to the Board of Health, and after its approval, to the Board of Estimate and Taxation and subsequently to a Representative Town Meeting

The plan would entail the hiring on full time of Dr Frederick Remer, present town bacteriologist, and the addition of more technicians to the health staff Dr Austin did not give any estimate of the cost of the project.

Fred J Loase, superintendent of Greenwich Hospital, at the committee session at the Department of Public Welfare, suggested that the Town pass an ordinance requiring periodical examination of food handlers, and Miss Georgiana B Davids, commissioner of public welfare, suggested health regulations for the periodical examination of all domestics

THE GOLF CHAMPIONSHIP OF THE American Medical Association was brought to Mount Vernon by Dr William J Van Wie who carded 75-73-148 in the title tourney of the organization held at the Seaview Club in Atlantic City The runner-up for low gross honors was another Mount Vernon player, Dr Edmund Sullivan with 77-74-151

DR ROBERT H SHANAHAN, chairman of the board of managers of the Yonkers City

Laboratory, and B W Petsche, a member of the board since its inception twelve years ago, have resigned their posts, charging "politics" in the Health Department.

Dr Shanahan also resigned as a member of the advisory board of the Health Department.

Although they declined comment, preferring their letters of resignation to Mayor Loehr "to speak for themselves," it was regarded by the local newspapers as "significant" that they decided to relinquish their posts twenty-four hours after the appointment of Dr Eugene F McGillian as Health Commissioner was announced by Mayor Loehr.

AN AMUSING REPORT of a medical athletic meet on June 22 appears in the *Portchester Item*. It runs as follows:

Greenwich surgeons performed a major operation yesterday upon the physicians of Greenwich in a soft-ball game at the Innis Arden Golf Club. The surgeons ran up a score of 37 runs. The physicians ran up a score of two runs and a high temperature.

The event was the annual outing and field day of the Greenwich Medical Society, a type of therapy designed especially for doctors. Dr Payson B Ayres produced symptoms of aggravated heart conditions with his hurling for the surgeons, but Dr Don J Knowlton, who twirled for the physicians, couldn't have found the plate with a stethoscope. He was roundly knocked out of the box in the pitcher's battle.

Dr Ayres, as a surgeon, was given the distinct advantage, being able, with skill and precision, to cut the corners of the plate. Dr Knowlton probed and diagnosed and couldn't find it, nor was he any more successful in the consultation that followed. He was taken to the emergency bench for treatment.

Dr William Burke served as umpire of the game, a thankless task, with only the ethics of the profession preventing him from giving his own diagnosis of the trouble with both teams.

With a perfect bedside manner, Dr Burke came out first on the green, winning a putting contest. Dr Thompson carried off the archery contest. Dr Albert E Austin led his band throughout the festivities. The dinner was served at the club in the evening, and prizes were presented to the winners of the day's events. Dr Thompson was elected president of the society, and Dr Reynolds, secretary-treasurer.

FREE TUBERCULIN tests have been ordered by Health Commissioner Eugene F McGill-

lian of Yonkers for all children brought to the city clinics for pre-school examination and treatment—whether at City Hall, the Health Center or the four welfare stations.

Yonkers thus becomes the "first community in the United States to extend tuberculin tests to pre-school children."

Wyoming County

DR GEORGE S SKIFF, of Gainesville, who was feted at a dinner on June 9 by the County Medical Society in celebration of his fifty years as a physician, died at his home on June 27. He was chairman of the board of managers of the Wyoming County Community Hospital.

Yates County

MORE THAN 500 members of the Lake Keuka Medical and Surgical Association held their 38th annual convention in Penn Yan on June 24.

The association includes 22 counties in New York and four in Northern Pennsylvania.

Following an address of welcome by Dr J Hillis Miller, president of Keuka College, Dr Henry J John of Cleveland read a treatise on "The Use of Protamine Insulin and Crystalline Insulin." A discussion of the paper by Dr John R Williams of Rochester, Dr Nelson G Russell, Dr Clayton W Green, and Dr Byron D Bowen, all of Buffalo, followed.

Dr Geza de Takats, assistant professor of surgery, University of Illinois, spoke on the diagnosis and treatment of convulsive seizures not due to epilepsy. His subject was discussed by Dr Allen O Whipple, New York, Dr S D Conklin, Sayre, Pa., and Dr A W Holmes, Penn Yan.

"The Carcinoma of the Right Colon: Its Diagnosis and Treatment," was the subject of Dr Claude F Dixon's speech. He is associate professor of surgery, Mayo Foundation, University of Minnesota. Six physicians led in its discussion—Dr Herbert A. Smith, Buffalo, Dr Arthur W Booth, Elmira, Dr John J Morton, Rochester, Dr E C Foster, Penn Yan, Dr A G Swift, Syracuse, Dr A. H Aaron, Buffalo.

Dr Stafford L Warren, associate professor of medicine, University of Rochester, presented a thesis on "The Indications and Contra-Indications and Results of Fever." Three doctors participated in the discussion. Dr Lee A. Hadley, Syracuse, Dr L M Lockie, Buffalo, and Dr C N Haines, Sayre, Pa.

Hospital News

The Labor Situation

IN VIEW OF THE almost nationwide reports of labor trouble in industry and of rumors of similar disturbances in hospitals, the Editor of *Hospital Management* addressed a letter to representative hospital executives in various parts of the United States asking for a brief report on local conditions. The replies were most gratifying in both the promptness of the response and in the news contained.

One-third of the replies were from sections in the east, south and midwest, and indicated a lack of trouble, either active or threatened. In the remaining parts of the country it was reported that there was union activity in many places, but that difficulties either had been or were being settled amicably. In only one section was any trouble anticipated. On the whole, the situation appears to be that on the part of the employees in the lower wage categories, requests or demands are being generally

made for increase in pay and improvement in working conditions, but the employees, whether unionized or not, are showing a spirit of compromise rather than of seeking trouble.

In the professional groups only one or two sections report any hint of unionization. The already existing organizations are looking after the interests of their members and from all parts of the United States come reports of movements for shorter hours and increased rates of pay.

On the part of the hospital administration there appears to be general recognition of the necessity of pay increases and changes in working conditions together with a genuine desire to adopt a fair schedule as rapidly as the financial situation will permit. From the general tone of the information received it is probable that there will be some friction in a few localities, but no serious trouble.

Workings of the Eight-Hour Law

THE CHANGE TO EIGHT-HOUR SHIFTS in the New York City hospitals on July 1 necessitated the employment of 2793 additional persons, according to Commissioner Goldwater. Of these 1100 in the non-nursing groups came from the WPA roles, but only 151 nurses were obtainable from that source. In its efforts to get nurses the department wrote to more than 1400 schools of nursing, made an extensive advertising campaign, and conducted recruiting drives in local districts, with very satisfactory results.

What the change means to the nurses is pictured by the Brooklyn *Eagle*, which sent a reporter to interview some of them in the Kings County Hospital.

Breakfast in bed sun bathing
time to read the papers and the movies

That's what the first consecutive eight-hour day meant to the nurses at Kings County Hospital, it says.

For many of these "ladies in white" the inauguration of the new working schedule meant real leisure for the first time in a

dozen years, so it was with unusual jubilation that they described to an *Eagle* reporter how they spent their first "time off."

Bridie Collins told how she got up at 9 o'clock instead of 6. She had breakfast at home and took her time over it. Then she visited some friends, then she took a walk in the sunshine and got to work at 3 P M.

"It's a grand world, seen all of a-piece, like that," she beamed. "You will feel that you are really living among people again. Why, I've been here for nine years and this was the first real time-off I've had. 'After the nice morning I spent I couldn't be irritable or crabby."

Anne Murphy got up at 9 and "ate eggs in peace for once."

"Why, I was 'a lady for a day,'" she exclaimed, "and when I got to work at 3 P M to go on duty for eight hours I felt like a new woman."

Grace Kearns declared "It wasn't what I had for breakfast, but that I had it at all. Afterwards I actually went out and bought some new uniforms."

Bernice O'Neill drew the early shift, which left her the evening to herself

She used to grab a cup of coffee and a roll for breakfast, but yesterday she dawdled over her repast for half an hour

"But it's after work that the fun will begin," she laughed, "I'm going to the

movies—imagine being able to go to the movies"

The atmosphere of "this freedom" extended even to the office of the superintendent of nurses Marion R. Doyle, head of the training school, Rebecca Taylor, her assistant, and Anne Walsh, were all smiles

The Hospital Staff and the County Society

HOSPITALS ARE COMING TO recognize more and more the advantage of selecting applicants for staff positions who are members of their County Medical Societies. The County Society can help the hospital in many ways, especially in its effort to raise the standards of its medical staff. As a matter of fact, says Dr. Joseph C. Regan, Chairman of the Membership Committee of the Medical Society of the County of Kings, in the Society's *Bulletin*, without county society membership, the hospital staff physician is, in most instances, inarticulate as a representative of any institution. The hospitals have not overlooked the legal protection provided for Society members in malpractice suits.

It is recognized that the "machinery" of the County Medical Society with its Board of Censors, its Comitia Minora and its many committees, actively working for the welfare of the physician, is most valuable and helpful to all hospitals in maintaining a high standard of medical ethics and a progressive and scientific attitude toward medical practice. Hospitals, therefore, have begun to ask applicants for professional appointment—"Are you a member of your County Medical Society?"

In order to learn the present policy of the various hospitals on the question of

County Society membership of their staffs, adds Dr. Regan, the following letter was addressed to the Hospital Superintendents under date of March 10, 1937

The Membership Committee would like to know what policy your Medical Board has adopted with regard to your entire professional staff (attending and courtesy) being members of their County Medical Societies. We would like to have this information on hand for comparative purposes.

Your cooperation in this matter will be greatly appreciated and if the Committee can be of assistance to you at any time, please call upon us.

Replies from nearly all of the hospitals have been received. The spirit manifested in these responses is one of great cooperation and interest.

The information obtained from the hospitals has been classified. The results are most encouraging. The Medical Boards of many of the institutions have already made it obligatory for applicants for staff appointments to be members in good standing of their county medical societies. In several hospitals the regulation is that the entire professional staff must be members of their county medical societies. Each day more data is coming in which shows increased activity on the part of the Medical Boards

Improvements

THE NEW \$1,250,000 BUILDING of the Jewish Memorial Hospital, at Broadway and 196th St., New York City, is practically completed and will be dedicated and opened before the end of the summer

• • •

THE CORNERSTONE FOR THE \$1,000,000 Frances Schervier Hospital and Home for the Aged at West 227th Street and Independence Avenue, the Bronx, was laid on June 20. The six-story building, already partly finished, will house 410 aged guests

and patients after it is completed at the end of the year

A CAMPAIGN IS ON to provide a complete newly equipped additional building for the Swedish Hospital in Brooklyn. The building was bought in 1929, but plans to equip and use it were halted by the depression.

PLANS ARE BEING MADE for a new addition to Beth-El Hospital in Brooklyn

The hospital is now overcrowded and has a waiting list for the first time since it was opened fifteen years ago

WASHINGTON HAS APPROVED a federal grant of \$382,500 to aid the construction of an \$850,000 addition to the Binghamton City Hospital, but as the prospect of raising the other half-million is somewhat clouded by doubt, a proposal is being made to add a forty-room private wing to cost \$100,000 and so planned that it can be included in the larger project later. Present accommodations are badly overcrowded.

THE \$168,000 ANNEX TO THE Oneida County Hospital at Rome was dedicated on July 1. It was financed by PWA and county funds.

THE \$80,000 PROVIDED FOR the maternity annex to the Jamestown General Hospital has been expended, and the annex is only fifty-five per cent completed, according to officials in charge of the work, as quoted in Jamestown papers. The Board of Public Welfare has asked for an additional appropriation of \$65,000 to complete it.

Newsy Notes

TOWNSEND HOSPITAL AT Gowanda has been changed from a privately-owned to a charitable institution.

ACTIVE FIELD WORK in Oneida's participation in the Central New York Hospital Service has been launched with Everett L. Baker as resident manager.

RED CROSS FLAG DISREGARDED

THE TRADITIONAL RED CROSS that marks the tents of wartime ambulance workers is disappearing from the modern battle field according to Dr. Edward H. Barsky, American surgeon who has returned to New York after establishing six field hospitals in Loyalist Spain.

"The modern field hospital has to be carefully camouflaged," he says. "Its windows have to be shielded to keep in light at night and prevent reflections in the daytime from making its position visible. This has become necessary because hostile aviators appear unable to recognize a red cross when they see one."

"Operating rooms are being built on wheels today," added Dr. Barsky. "They can thus be more quickly moved wherever they are wanted." He will return to Spain in September, he hopes, with more volunteer ambulance units.

The American hospitals, four of them near Madrid and two on the Cordoba front, were established at a cost of \$118,045 and are manned by ninety-nine American sur-

geons and nurses, with much larger Spanish staffs under their supervision.

All these hospitals are now directed by Dr. Donald H. Pitts, former U. S. Army Surgeon of Elk City, Oklahoma, who replaces Dr. Barsky.

The first six months work of the American medical units has met with the highest approval of the Spanish Health Ministry and is regarded as a model of the hospitals from various countries operating in Spain today.

"We feel proud of the achievements of our people in Spain and the high praise of the Spanish government," Col. Crookston, executive secretary, says. "It is good also to know that when Spanish and American soldiers with the Loyalist forces talk about being hit, they hope they will be sent to the American hospitals. But it is even more encouraging to hear however, that our hospitals have saved thousands of lives of not only the combatants, but also many women and children, innocent victims of war."

OBEDIENCE BY DISOBEDIENCE

THE NEW YORK CITY Department of Hospitals has been able to obtain enough additional nurses to inaugurate the eight-hour day only by ignoring a requirement of the State Education Department, Commissioner S. S. Goldwater discloses.

The Education Department has a rule that hospitals which operate schools of nursing may employ only nurses holding New York State registrations.

The Department of Hospitals, to obtain State charters for its nursing schools, has complied strictly with this rule in the past. But it isn't complying with it any longer.

Forty per cent of the 750 nurses added to the city's staff in the last two or three weeks came from other States, Dr Goldwater said. The department, is accepting their registrations in those States as proof of their eligibility for employment here.

"We couldn't do otherwise under the circumstances," Dr Goldwater said. "It was impossible to get in New York State anything like the number of additional nurses we required."

He added that he thought the State Educational Department "would be lenient."

"Some of the private hospitals which have nursing schools also have been forced to take nurses from other States. The violation of rules has been tacitly condoned and their nursing school charters have not been suspended," he said.

Dr Goldwater originally estimated that 1,281 additional graduate nurses would be needed to enable the department to put the eight-hour law into effect. So far only about 750 have been obtained. But the shorter working hours are now observed in all city institutions, it was stated.

THE ASSOCIATED HOSPITAL SERVICE, of New York City, has paid \$1,500,000 to 240 member hospitals in the metropolitan area in two years. Its membership has passed the 400,000 mark.

THE OPERATING LOSS of the New York Hospital was reduced from \$1,070,262 to \$914,646 in 1936, according to the 165th annual report. The 1935 deficit was reduced by more than 50 per cent in 1936.

"Greater efficiency and savings in cost of operation," said Henry G Barbey, president of the society, "account for only a share of the better results. Increased income, both operating and non-operating, has been a major factor. Legacies and special gifts received during the year far exceeded the amount drawn from general funds to meet the current expenses."

With its affiliated units, the Society of the New York Hospital cared for a total of 18,733 bed patients and 46,016 out patients during the year.

A LADIES AUXILIARY for the Grey Oaks Hospital, Yonkers city institution for tubercular patients, was organized in July.

At the Helm

Mrs THOMAS V D BUDD was re-elected president of the Northern Dutchess Hospital Auxiliary at the annual meeting.

FORMAL APPOINTMENT OF Dr John K Deegan as superintendent of the new Herman M Biggs Memorial Hospital is announced by Dr Edward S Godfrey, Jr, state commissioner of health. Doctor Deegan has been identified with the state division of tuberculosis for more than four years, and has served as acting physician in charge of the Biggs Hospital since it was first opened a few months ago.

Dr. R G WILSON has been elected president of the medical staff of St Jerome's Hospital in Batavia.

THE DISCOVERY OF LARGE DEFALCATIONS

by a too-much trusted employee has caused something like an earthquake in the affairs of the Jamestown General Hospital, and Dr John S Hickman has been placed in full control of the institution, with power to appoint and remove any persons connected with it.

THE FOLLOWING HOSPITAL OFFICIALS HAVE BEEN ELECTED

John L O'Connor, to be president of the A Barton Hepburn Hospital at Ogdensburg.

A C Saunders, to be president of the Nathan Littauer Hospital at Gloversville.

Max DeKaye, to be president of the Brooklyn and Long Island Hospital Council.

William J Bradford, to be president of Huntington Hospital.

LORENZ J. BROSNAN, Esq.

Counsel, Medical Society of the State of New York

Evidence—Opinion Testimony Based Upon False Hypothesis

An attempt to make out a case of malpractice against a physician based upon assumptions rather than facts established by testimony was the subject of an interesting case recently brought before an Appellate Court in one of the Pacific Coast States *

The action was brought by the husband and daughter of B to recover damages for her death which was claimed to have been caused by the negligence of C, a physician. The complaint charged that the defendant had been employed to administer an anesthetic during an operation for the removal of the appendix and drainage of the gall-bladder of the patient. The charge was that defendant had negligently given the anesthetic so that an insufficient supply of oxygen was administered with ethylene gas, carbon dioxide gas, and ether, with the result that the patient met her death by asphyxiation.

It appeared that toward the completion of the operation it was noticed that the anesthesia had become too light, and the operating surgeon requested that Doctor C provide a deeper anesthesia. C then noticed that the oxygen from the oxygen tank was rapidly becoming depleted, and he called upon a hospital orderly for a fresh supply of oxygen. Another tank was provided and about five minutes was consumed in getting the new tank connected. During that interval the ethylene gas was not shut off, and the patient remained under anesthesia. The mask remained on or over the patient's face. At about the same moment that the fresh oxygen was administered the patient ceased to breathe, and it was impossible to revive her.

The defendant's theory of the cause of death was that it was brought about by heart failure and surgical shock unrelated to the anesthesia. He testified that while the tanks were being changed he kept his fingers under the edges of the mask so as to permit the patient to breathe oxygen from the air. The testimony of witnesses present as to whether the anesthetist so raised the mask was conflicting.

The uncontroverted testimony as to the symptoms of the patient preceding death was significant. The last blood pressure reading taken five minutes before cessation of breath-

ing showed a marked drop in the systolic blood pressure from 135 to 105. Normal breathing continued up until the time breathing stopped, and cyanosis followed cessation of respiration.

The trial resulted in a verdict for the plaintiffs. The verdict was based solely upon the opinion testimony of a certain Doctor T, called as expert for the plaintiffs who in answer to a hypothetical question gave it as his opinion that death resulted from asphyxiation.

Upon an appeal from the judgment of the trial court, the testimony so given by Doctor T became the turning point of the entire matter and it was found by the Appellate Court that his testimony was based upon a false hypothesis and was of no weight whatsoever as opinion evidence of the cause of death.

The Appellate Court, reviewing the record found it to have been uncontroverted from the testimony that the symptoms of an over dose of ethylene gas are cyanosis before death, labored, rapid, shallow breathing, and a drop in blood pressure following cessation of respiration. It was testified that in asphyxiation cessation of respiration would not precede a drop in blood pressure, and that a drop in blood pressure prior to cessation of respiration would indicate heart failure.

The hypothetical question, however, which was put to Doctor T, plaintiffs' expert, assumed that the blood pressure readings were normal during the anesthesia and omitted reference to the last reading. The question also failed to assume normal breathing up to cessation of breathing. The hypothetical state of facts also assumed that cyanosis occurred before breathing ceased. However, upon the hypothesis as given had been based the only testimony to in any way support a finding that Doctor C had been guilty of malpractice. Doctor T in fact had upon the trial made the following concession: "It is my opinion that in death by suffocation, respiration would cease and the blood pressure would drop following, whereas in death from heart failure the blood pressure would drop before respiration ceased."

In reversing the judgment of the lower court, the Appellate Court said in its opinion

**Forbis v. Holzman*, 45 Pac. (2nd) 215

No one can doubt the extreme difficulty encountered by a jury or trial judge in an endeavor to determine the true cause of death in a case such as this. They are entitled to receive the honest opinions of expert witnesses, predicated upon facts established by the evidence, and the opinions are of no value if they are based upon essential facts which are not given in evidence, upon facts which are directly contrary to the evidence, or upon statements omitting facts which are important, if not necessary, for the witnesses to take into consideration in formulating their opinions. Intentional unfairness need not exist to justify the rejection of such evidence. The result is the same if the fault lies in honest mistake or in an excess of zeal to achieve the desired result. The questions asked may be unfair, and the answers may be unfair, if based upon a wrong hypothesis, notwithstanding the good intentions of counsel and witness.

The foregoing considerations condemn the testimony of the witness T and brand it as a type of opinion evidence unworthy of credence and unacceptable as evidence. The hypothetical case as to which his opinions were given was not that of Mrs B.

We give full recognition to the rule that a very considerable latitude is allowed in the statement of hypothetical facts calling for opinions from expert witnesses. Such statement need not contain all of the facts testified to and of course, it may assume facts most favorable to the theory of the party for whom the witness is testifying. There may be an allowable variation between the facts assumed and the actual facts proven. But it is said in this case that the opinion can have little, if any, value unless the material facts assumed in such question are substantially true.

Where the material facts upon which the opinion is based are untrue, and the erroneous hypothesis is disclosed by the questions, or by the answers of the witness or by his testimony on cross-examination, the opinion itself becomes false and misleading. It tends to obscure the truth and to lead juries or courts into erroneous conclusions of fact. Opinion evidence lacking a true foundation of fact is incompetent. It carries no weight in the trial of a case and carries none when considered on appeal. A finding based wholly upon such incompetent evidence is without support.

Diabetic Gangrene

A doctor engaged in the general practice of medicine, at the request of an older practitioner, took over the latter's practice while he went on a vacation. Among the patients who came under the care of the substitute

physician was a man fifty-six years of age, who had been under insulin treatment for diabetes. The doctor first saw the patient when he was called to his home and found him in bed complaining of pain in his right leg, toes, and groin. The doctor ascertained that the patient had been giving himself the daily injections of eight units of insulin and that he was keeping within a prescribed diet. Examination showed the toes and foot to be swollen and on the dorsum of the second toe of the right foot thick, yellow pus was exuding from an opening in the skin. X-rays were taken and said report showed that the bones of the foot and toes were normal but that the patient was suffering from a soft tissue infiltration. The doctor advised the patient to remain in bed, continue with the insulin, keep to his diet, and avoid all exercise. He saw the man a day later and his pains had increased. The ulceration had not improved and the doctor advised hospitalization and gave him a note for the purpose of entering the hospital. He increased the insulin from eight to ten units daily and advised the patient that if he did not go to the hospital, to purchase a heat lamp, and gave the man instructions as to the manner of using such lamp.

The last time the doctor heard of the case was when the patient visited him at his office the following week. Again examination showed the condition to be no better and the patient was advised to go to a hospital, which the patient promised to do. The doctor never saw the patient thereafter.

It was later found out that within two days from the time the doctor last saw the patient he entered a hospital with a diagnosis on admission of diabetic gangrene of the right foot. A large gangrenous ulcer on the dorsum of the foot was treated and after a considerable period of time the patient's leg was amputated at the mid thigh.

A malpractice action was instituted against the physician charging him with having negligently treated the case and also charging that he was responsible for the fact that the plaintiff's leg was eventually amputated.

The case came on for trial before a judge and jury and at the conclusion of the testimony of the plaintiff's witnesses, the case was dismissed on motion of counsel for the defendant, upon the grounds that the plaintiff had failed to establish a *prima facie* case of malpractice against the defendant.

The American Congress of Physical Therapy will hold its sixteenth annual session in Cincinnati, Ohio, on September 20 to 24.

America does not want a medical system run by non-medical people who could not tell the difference between an X-ray and an electrocardiogram.—*New York Sun*

Across the Desk

Revolt of the Guinea Pigs

WISCONSIN PEOPLE HAVE DECIDED that they do not care to act as guinea pigs to test the workings of compulsory sickness insurance. On June 17 the Wisconsin Assembly, by the thumping majority of sixty-three to twenty-seven, voted down the Biemiller bill that would have saddled socialized medicine upon the state. The feeling went around that the plan would make the people play the role of mice, guinea pigs, or rabbits in a socialistic medical experiment backed by big foundations, and they revolted. The accompanying cartoon, from a leading Wisconsin newspaper, shows how they felt.

The alarm, in fact, spread to neighboring states, Milwaukee papers reported that the group of seven Biemiller Medical bills before the Wisconsin legislature would next be introduced in the Minnesota legislature, and *Minnesota Medicine*, organ of the state medical society, printed a warning editorial headed, "Are we to Serve as Guinea Pigs?" Minnesota is safe from such attacks, in the opinion of its state medical journal, but if Wisconsin had yielded, there can be little doubt that the powers behind the movement would have gone on to try their wiles on any state that was handy, and we may be certain that next winter will see the battles renewed at many state capitals.

Let the Weak-kneed Cheer up

Weak-kneed people in the profession who have been saying, "Oh, socialized medicine is bound to come," might do well to take a look at what went on at Wisconsin's capital. Most of the speakers at the hearings on the group of bills favored them. A clergyman from northwest Wisconsin devoted part of his remarks to vituperative attacks upon the medical profession. Almost the only opponent of the bills before the committee was George Crownhart, executive secretary of the State Medical Society, yet the committee voted four to two against the bill for socialized medicine, and it went down to disaster, as noted above, in the vote in the Assembly.

Wisconsin is considered a liberal, if not a radical, state, but it has no intention of being the guinea pig for the socialized medicine experiment. One of the members of the committee was a physician, Dr. Joseph L. Barber, and in the course of one of the hearings he interrupted an advocate of the bills and said "You know in your own heart this is merely communism all the way through, and why should you come into the Wisconsin Legislature with such junk as this?" The lawmakers evidently agreed with him.

A Lopsided Scheme

The scheme was to apply compulsory sickness insurance to all employed persons earning \$60 a week or less. It was fathered by the labor unions, and the executive secretary of the State Medical Society very ably drove home the point that it would provide medical care for only about half the state's population, but that if it ran up a deficit, as he figured likely, the other half would have to foot the bill. Many members were deluged with letters and telegrams urging them to vote such a lopsided scheme down. One rural member exclaimed "So the farmers are to be left out in the cold in order that labor may secure the benefits!"

The legislature even failed to vote on a bill calling for an interim committee to study the costs of medical care, and it died when the lawmakers adjourned. The general view was well summed up by Assemblyman Cavanaugh, who pointed to the high service rendered the people of the State by the family physicians.

"I speak on this subject out of my personal experience," declared Mr. Cavanaugh, "our family for years has had such a family physician. The people of Wisconsin do not need this bill. It is a proposal based only on theory. As far as the people are concerned, as I know them, I know that the old way is better because of the fact that they are well taken care of medically by those who know them and

who cherish the family relationship. There is no one who needs medical protection. If we have this system it will provide nothing but a further burden on the taxpayers of this State."

A.M.A. Journal notes, fall into three classes (1) to force governmental and tax-exempt hospitals to permit all practitioners of the healing art, no matter whether they are physicians or practitioners

From the *Milwaukee Journal*
Guinea Pigs for a New Experiment?

A Nationwide Battle

The battle, indeed, has been raging all over the country in the state legislatures to pass needed medical laws and to fight off legislation damaging to the health and welfare of the public. The cult practitioners particularly are tireless in efforts to secure legislation to benefit their selfish interests. The cult proposals, as the

of bizarre cults, to practice within their confines, (2) to authorize osteopaths, chiropractors, naturopaths and other sub-standard practitioners to care for, at the employers' expense, workmen injured in the course of their employment, and (3) to force public officials, charged with the duty of furnishing medical care to indigents and other persons on relief rolls or un-

The alarm, in fact, spread to neighboring states, Milwaukee papers reported that the group of seven Biemiller Medical bills before the Wisconsin legislature would next be introduced in the Minnesota legislature, and *Minnesota Medicine*, organ of the state medical society, printed a warning editorial headed, "Are we to Serve as Guinea Pigs?" Minnesota is safe from such attacks, in the opinion of its state medical journal, but if Wisconsin had yielded, there can be little doubt that the powers behind the movement would have gone on to try their wiles on any state that was handy, and we may be certain that next winter will see the battles renewed at many state capitals.

Let the Weak-kneed Cheer up

Weak-kneed people in the profession who have been saying, "Oh, socialized medicine is bound to come," might do well to take a look at what went on at Wisconsin's capital. Most of the speakers at the hearings on the group of bills favored them. A clergyman from northwest Wisconsin devoted part of his remarks to vituperative attacks upon the medical profession. Almost the only opponent of the bills before the committee was George Crownhart, executive secretary of the State Medical Society, yet the committee voted four to two against the bill for socialized medicine, and it went down to disaster, as noted above, in the vote in the Assembly.

Wisconsin is considered a liberal, if not a radical, state, but it has no intention of being the guinea pig for the socialized medicine experiment. One of the members of the committee was a physician, Dr. Joseph L. Barber, and in the course of one of the hearings he interrupted an advocate of the bills and said "You know in your own heart this is merely communism all the way through, and why should you come into the Wisconsin Legislature with such junk as this?" The lawmakers evidently agreed with him.

A Lopsided Scheme

The scheme was to apply compulsory sickness insurance to all employed persons earning \$60 a week or less. It was fathered by the labor unions, and the executive secretary of the State Medical Society very ably drove home the point that it would provide medical care for only about half the state's population, but that if it ran up a deficit, as he figured likely, the other half would have to foot the bill. Many members were deluged with letters and telegrams urging them to vote such a lopsided scheme down. One rural member exclaimed "So the farmers are to be left out in the cold in order that labor may secure the benefits!"

The legislature even failed to vote on a bill calling for an interim committee to study the costs of medical care, and it died when the lawmakers adjourned. The general view was well summed up by Assemblyman Cavanaugh, who pointed to the high service rendered the people of the State by the family physicians.

"I speak on this subject out of my personal experience," declared Mr. Cavanaugh, "our family for years has had such a family physician. The people of Wisconsin do not need this bill. It is a proposal based only on theory. As far as the people are concerned, as I know them, I know that the old way is better because of the fact that they are well taken care of medically by those who know them and

must know." It then listed the bills favored by the Medical Society and gave the name and post office address of every member of the State Senate and House, and said, "You are urged to study the entire legislative program and make known your wishes to as many Senators and Representatives as you know—through personal interviews if possible, or by letters and telegrams. Please do it now. We have been told by some legislators that the reason we do not get more laws for the benefit of all the people, including doctors, nurses, and hospitals, is because they (the legislators) do not know what their doctors want."

As a result, five important bills favored by the Medical Association were passed and four bills opposed by the Association were defeated.

The Secretary-Treasurer of the Medical Association of Georgia, Dr. Edgar D. Shanks, who sends us this information, says in his letter "We are copying after your state in the matter of public relations," and we find among the recommendations of the

Committee on Public Policy and Legislation the following:

Chiropractic is the science of locating and removing any interference with the transmission of nerve energy. A license granted under the provisions of this Act shall not entitle a licensee to use drugs, surgery, osteopathy, obstetrics, dentistry, optometry nor chiropody.

Nor is that all. "Finally," we read, "our committee recommends that each component county medical society in the state sponsor a candidate for a legislative post, preferably one of its own members." If successful, this move forshadowes an ideal state where the laws will be made by a legislature made up solidly of the men of medicine. State after state, and state after state, will perhaps fall in line, the Congress will follow suit, and all our political ills, infections and disorders will have a thorough going treatment by the men who know how to diagnose what is wrong and put it right. The M.D.'s are only just beginning to get their hands in on this political game, and it may not be long now before the old-line politicians will be sorry they attracted the doctor's attention.

AN EVASION RACKET IN CALIFORNIA

Courts have decreed that corporations cannot practice medicine or contract to supply medical service. This ruling has terminated attempts on the part of certain compensation insurance companies from openly employing medical men on a monthly salary basis to render medical care to the employees of firms covered by their insurance coverage.

Reports now are on hand that these certain insurance companies have resorted to a new undercover form of law evasion says *California and Western Medicine*. This evasion is operated in the following manner: The company engages usually a young surgeon on a monthly salary basis. Instructions are given him to rent ample quarters, engage nurses, a stenographer to make out records and reports, purchase physiotherapy equipment, etc. Firms covered by this company are instructed to send injured employees to this hired agent surgeon. The surgeon is instructed to bill the company on the first of the month for all services rendered at compensation fee schedule rates. By the fifth or the tenth the surgeon receives

a check but he is instructed not to cash this check. In a day or so a company representative calls and picks up this check. He gives the surgeon cash or draft to pay rent, monthly pay roll and office overhead and surgeon's monthly salary. This later transaction is, of course, under cover and the surgeon can claim he is doing compensation work under fixed approved fee rates.

The scheme is illegal, evasion of laws, contract practice and insurance company corporate practice. The surgeon makes himself liable to revocation of his license and the insurance company to illegal corporate practice penalties.

The matter has been called to the attention of the Compensation Commission, the Insurance Department and the Board of Medical Examiners. Steps will be taken to end this racket. Members are requested to send in information that they may have so that it may be turned over to investigators. Such reports will be held in confidence and the informant will not become involved. Members should aid in terminating this corporate racket.

able to pay for such services, to permit cultists to treat such persons at public expense

Some Crumbs for the Cultists

Despite the most strenuous efforts, the cultists have had very little success. A bill to license chiropractors passed the Delaware legislature and was signed by the Governor. There are said to be about thirty chiropractors in Delaware. The Governor said in an explanatory letter to the editor of the *Delaware State Medical Journal* "Without going into the merits of this profession, its practice has been in effect so long that the public has recognized it and many people believe in it and have assured me that they or some of their families have been benefitted by this treatment.

"Both bodies of the Legislature believed that the profession should be recognized and the public safeguarded from inefficient and improperly trained practitioners. Members of the General Assembly personally solicited me to sign this bill, having received treatment from various members of the profession.

"We should all realize that chiropractors are with us to continue their profession indefinitely, therefore, believing it the best thing to do I approved the bill which calls for a Board of Examiners."

Section 8 of the act however makes these restrictions

That the Medical Association of Georgia establish at the office of the Association in Atlanta a Public Relations Bureau similar to that now operated by the Medical Society of the State of New York

The Public Relations Bureau of the Medical Society of the State of New York states "The public needs to be told what are their questions, and they must be told the answers, and, finally, they must be persuaded to act in accordance with the answers." Such a Bureau prepares informative and persuasive medical material for publication in the weekly newspapers, and furnishes confidential information to each member of the State Medical Association as the need arises. In Georgia there are 225 weekly newspapers

Another reverse was experienced in Kansas, where a Basic Science Law was passed, but was unfortunately so amended that it exempts osteopaths, chiropractors, and all other practitioners who are now regulated

by their state board examiners "Yet the battle was not in vain," declares the *Journal of the Kansas Medical Society*, for "several other branches of the healing arts do not have state board examiners, therefore their representatives who meet the requirements of this law may gracefully present themselves to the public with their qualifications"

Basic Science Laws Passed

In Michigan, President Henry E. Perry of the State Medical Society transferred his residence to Lansing for five months to help the passage of the Basic Science Law and to keep destructive proposals off the statute books, and was rewarded with success in both efforts. In his message of congratulation to the State Society, he remarks especially that "praise and gratitude are forthcoming to family physicians of legislators," who "labored valiantly" in behalf of the Basic Science Bill.

"Three rousing cheers" are called for by *Colorado Medicine* to celebrate the legislative victory there. "After eight years of increasing effort," it says, "a Basic Science Law has been passed by the General Assembly of the State of Colorado, and a legislative season has closed without passage of a single medical or public health law opposed by this organization!" The one fly in the ointment is an amendment to the Basic Science Law which recognizes medical cults to the extent of including one Doctor of Osteopathy and one Doctor of Chiropractic on the five-man Basic Science Board. But the principle of the law is preserved. All who practice the healing art, under any name, must demonstrate their knowledge of the basic sciences. And, we are told, "this is certain none of the bizarre new healing cults which seem to be gaining recognition in some states will ever get so much as a toe-hold in Colorado so long as this Basic Science Law is on the statute books." It is certainly a fine showing, and we may consider the three rousing cheers as given.

Georgia's Noteworthy Plan

A plan worth noticing was operated by the Medical Association of Georgia. In February, its *Journal* carried a pink supplement headed "Write your legislators today. They

MATERNAL MORTALITY IN ERIE COUNTY, N Y

Report of a Survey by the Maternal Mortality Survey Committee of the
Erie County Medical Society

MARVIN ISRAEL, M D, *Buffalo*, Chairman

Introduction

On April 16, 1934 the Medical Society of the County of Erie adopted a resolution to conduct a survey of maternal mortality in Erie County and to institute the necessary measures to make child bearing relatively safe. In accordance with this resolution Dr James Borrell, president of the Society, appointed a Steering Committee of eleven members and a chairman with the power to consult advisory groups both lay and medical as indicated.

The following were the committees

Steering Committee

Marvin Israel M D, Chairman
Francis E Fronczak, M D Frank H Long M D
Iran Hekimian, M D Lewis F McLean, M D
Allen A. Jones M D Alfred H Noehren, M D
William H Jones, M D W Ward Plummer, M D
Edward W Koch, M D Margaret Warwick, M D
Leon J Leahy M D

Obstetrical Study Group

Edward Forrester, M D Irving Potter M D
William Getman, M D * Louis Siegel M D
Edith Hatch M D Harry LaForge M D.,
Investigator
Francis Goldsborough M D Chairman
* Died February 20 1936

The Chairman wishes at this time to extend thanks on behalf of the Society to all committees for their sincere and interested services. Dr Fronczak kindly placed at our disposal the services of Mr Delmer Bacheller at that time Health Department Statistician. To Mr Batcheller we extend an especial note of appreciation for the many hours of unstinting and

Heleen Hinckley, R.N.

Various types of assistance were received from the following groups Hospitals Child Health Week Committee The Buffalo Foundation The Buffalo Tuberculosis Association Buffalo Health Department, New York State Department of Health, The Connors Foundation

Report

The necessity for the survey was demonstrated by the following

- A The maternal death rate for Buffalo in 1932 was more than double that of Rochester, New York, and 15.5 higher than that of New York City (Chart I and Table I)
- B The 55th Annual Report of the Department of Health, State of New York states on Page XLIX—5th Paragraph "Among the cities of over 50,000 population Buffalo had the highest rate (68.0) "

The objectives formulated at the time were

valuable service often given until late at night in the compilation and statistical interpretation of our data. Also our thanks are due to Dr Archibald Dean District Health Director of the New York State Department of Health for his valuable cooperation. Miss Kerr of the Buffalo Foundation gave much helpful advice on the organization of the Survey.

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

An Introduction to Medical Science By William Boyd, M.D. Octavo of 307 pages, illustrated Philadelphia, Lea & Febiger, 1937 Cloth, \$3.50

This Volume of three hundred pages is concise, accurate, well written, and contains much information. The author starts from fundamental facts and develops them logically into the organs and functions of the human body. Part I deals with the nature and causes of disease, inflammation, immunity, allergy, bacterial infections, animal parasites and tumors. Part II deals with the systems of the body and their diseases. This is a good, brief, reference book written not only for students but also for nurses.

HENRY M. MOSES

A Manual of Pharmacology By the late Walter E. Dixon, M.D. Revised by W. A. M. Smart, M.B. Eighth edition. Octavo of 483 pages, illustrated. Baltimore, William Wood & Company, 1936 Cloth, \$6.50

As a fitting tribute to the late author, W. E. Dixon, this new eighth edition of his manual appears. A complete recast of the previous edition has brought the book thoroughly up to date and in line with current trends and thought in the field of pharmacology.

This edition places more emphasis upon a knowledge of organic chemistry which is coming to play an increasingly important role in pharmacological research. The generous supply of structural formulas and relationships, and the liberal insertion of prescriptions add to the practical value of the book for the research pharmacologist and young physician. A further highly commendable feature is the number of valuable tracings, most of which have been retained from the previous edition.

However, it lacks completeness of discussion and detail which is generally desired in a textbook for medical students, the section on the endocrines being particularly inadequate. A bibliography would be a welcome addition. The greatest value of the manual is in its use as a convenient reference book for the practising physician or research pharmacologist. The material is concise, accurate and up to date.

J. RAYMOND JOHNSON

The Operations of Surgery By R. P. Rowlands, F.R.C.S. & Philip Turner, F.R.C.S. Eighth edition, Volume II, The Abdomen. Quarto of 998 pages, illustrated. Baltimore, William Wood & Company, 1937 Cloth, \$10.00

This second volume of the eighth edition of this work is devoted to surgery of the abdomen.

It is seldom that a book has as much valuable information unclouded by non-essential descriptions and obsolete material. The illustrations are all to the point and do not suffer from unnecessary diagrammatization. The anatomical surveys preceding each operation are to the point and most adequate.

The highest praise the reviewer can give this book is the advice to every surgeon to have it within reach on his desk.

GEORGE WEBB

The Diseases of Infants and Children By J. P. Crozer Griffith, M.D. and A. Graeme Mitchell, M.D. Second edition, revised and reset. Octavo of 1154 pages, illustrated. Philadelphia, W. B. Saunders Company, 1937 Cloth, \$10.00

As a textbook and general reference book in studying diseases of infants and children, this 1937 edition probably cannot be surpassed. Already becoming a very popular volume, the authors have brought in certain innovations to enhance its value. For instance, putting in smaller type certain topics and explanations of interest only to the teacher and student, and emphasizing salient points by means of italics, are immense aids to the reader. Another improvement is the listing of references at the end of chapters instead of having each page cluttered with material more or less useless to the majority of readers.

Illustrations are plentiful and the addition of colored plates not only beautify but make the text more instructive.

Especially well handled is Section III dealing with general nutritional, metabolic and miscellaneous diseases. Under this heading such diseases and conditions as rickets, allergy, the rheumatic state, acidosis and alkalosis, diabetes, the common poisons, etc., are briefly yet eruditely presented.

THURMAN B. GIVAN

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St., N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

Health furnished copies of the death certificates for county deaths. For each death the special investigator filled out Revised Form C B-122 of the U. S. Children's Bureau-U. S. Department of Labor, getting his information from physicians and records. This information was utilized by the Obstetrical Study Group in its study of the classification of maternal deaths.

A Subcommittee on Nursing Standards was also appointed which, through questionnaires submitted to each hospital accumulated data from which this subcommittee drew its special report on Obstetrical Nursing in this community.

Cooperative activities were also inaugurated. Recognized previous surveys and students of the subject had stressed certain objectives as of paramount importance. Among these objectives was the education of the Public. Existing surveys indicated that the chief dangers to mothers' lives involving the responsibility of the public came from the following:

- (a) Failure of the patient to cooperate with her physician during pregnancy
- (b) Failure of the patient to obtain prenatal care or to realize its importance or to understand what constitutes a minimum standard of prenatal care.
- (c) Danger to mother's life from abortions (at least one-fourth of all maternal deaths in previous surveys were found to be due to abortions)
- (d) Demanding painless childbirth at unwarranted risks

In view of these findings, the Committee recommended that the Society enter into a public education campaign in cooperation with the Buffalo Child Health Week Committee. Through leaflets, exhibits, public speakers, and radio broadcasts the public has been informed on these points.

The hospitals have sent to the Committee yearly reports of their obstetrical data which have been compiled as rapidly as they have been received.

Supplemental birth information was considered a necessity because previous Maternal Mortality Surveys lacked a study of delivery methods in cases where the mother survived. The Committee deemed this study essential to its survey.

Therefore, in cooperation with the Department of Health of Buffalo, the following form was decided upon:

DIVISION OF VITAL STATISTICS,
DEPARTMENT OF HEALTH
Buffalo, New York

Supplementary Information for Birth Certificate

Name _____ Registration No. _____

Date of Birth _____

Character of Delivery as follows Check ()

NORMAL (Spontaneous)
OPERATIVE

Forceps _____ Low _____ Version _____
Mid _____ Caesarian _____
High _____ Breech _____
Other Operative (Specify) _____

This supplemental birth sheet was circulated to each physician doing obstetrical work and to the hospitals. Since July 23, 1936, this information has been printed on the Birth Certificate, across one end as can be seen in Chart II.

Based upon the information thus obtained, the Committee submits herewith tables covering the period from June 1, 1935 to August 31, 1936 inclusive, covering 12,747 births, together with a statistical analysis thereof (Tables II-VI). A translation of these figures into conclusions with recommendations justifies their compilation.

The Relation of Obstetrical Procedures to Puerperal and Neonatal Mortality is set forth in the following statistical analysis by Mr. Delmer E. Batcheller, formerly Registrar of Vital Statistics of Buffalo.

On June 1, 1935, the Division of Vital Statistics of the Buffalo Department of Health, at the request and with the cooperation of the Medical Society of the County of Erie, began collecting data on the delivery methods employed by physicians in that city. A mimeographed form was sent to each attendant at a birth delivered in the home, requesting him to check the method employed, to the various hospitals, lists of all births reported were mailed monthly to secure the same information.

The response was immediate and gratifying. During the fifteen month period between the date of the beginning of the study and August 31, 1936, there were registered in the city 12,339 live-births and 408 still-births, of these 12,747 births, delivery reports were received on 11,780, or 92.4 per cent. As was perhaps to be expected, the returns from the hospitals

section, 31, is unusually high or low, it would be necessary to have a complete case study of a large number of unselected births, to determine the proportions of cases in which the indications for such an operation occur in a random sample of pregnant women. On the basis of the data here presented, this proportion seems high, but such an opinion cannot be categorically expressed without much further study.

Puerperal Mortality

Table III shows the puerperal mortality during the fifteen month period. To obtain these data, the death certificates of all women of child bearing age reported to the Division during the period were checked against the recorded birth certificates registered during the two months preceding the death, certificates recorded as caused by criminal abortion are also included, although these are classified as homicides. Since there were no maternal deaths following deliveries reported as "High Forceps," or "Others," these are omitted from the table. Two of the deaths in the column "Not Known," followed deliveries occurring before the study began.

This table also includes the Standard Errors of the rates for total deaths by each method, these are included to indicate how much reliance may be placed on these calculated rates. To obtain these standard errors, two assumptions have been made, the validity of which may be questioned,

1 That the deaths in these samples follow the binomial law of distribution.

2 That each group is homogeneous, and consequently follows the law of simple sampling. It is believed, however, that the Standard Errors derived in accordance with these assumptions, are conservative statements of the variance of these rates. If, as seems possible, these distributions follow the Poisson rather than the binomial law, the standard errors as stated represent a maximum.

The ratio of the rate to its Standard Error is a measure of the reliability of the former. The probability is about ninety-eight in one hundred that another similar sample will give a rate within twice the Standard Error of the rate as determined from the data at hand, hence, if this ratio of the rate to its Standard Error is less two, the rate must be regarded as unreliable. According to this criterion, the puerperal mortality rate following forceps deliveries and breech presentations are not to be construed as representative rates.

In order to compare the various rates with each other, Table IV is presented, showing the so-called "Critical Ratios" of these differences, that is the ratios of these differences to their

Standard Errors. In constructing this table, the same assumptions are made as were used in computing the Standard Errors of the various rates. In presenting this table, midforceps deliveries and breech presentations are not included, because of the unreliability of the original rates. The criterion for judging these critical ratios is the same as that for interpreting the reliabilities of the original rates.

From Tables III-IV the following conclusions may be drawn

1 There are definitely more puerperal deaths, both absolutely and relatively, in hospitals than at home. This is undoubtedly largely accounted for by the fact that serious cases are taken to hospitals for emergency care.

2 Death rates following major operative technics (version and cesarean section) are definitely higher than those following normal and low forceps deliveries, also, the rates following cesarean sections are definitely higher than those following versions.

3 From the data given no categorical statement can be made that major operative procedures are causes of higher puerperal mortality rates, it can definitely be stated, however, that the two are highly correlated, that greater chance for the mother's death is associated with greater use of such technics. The real cause of such deaths may be the procedure used, on the other hand, it is equally likely that the complicating conditions which lead to the use of such measures would have caused death in any event. It is probable that the use of these methods has prevented many deaths.

The presence of this high degree of correlation between major operative technics and a high maternal mortality rate complicates rather than simplifies the procedure. In order adequately to determine the relation of such obstetrical methods to the death rate, a statistical study of complicating factors in a large number of unselected cases should be made. Only after such a controlled study, eliminating the effect of such factors, can definite conclusions regarding the importance of such technics as causes of death, per cent, be judged.

In connection with this question of primacy of delivery methods as causes of death, it is noteworthy that the scheme of classification of death certificates of puerperal deaths given in the Manual of Joint Causes of Death, the official standard of the Census Bureau, gives precedence to the complicating condition for which the operative technic was used, rather than to the operation itself.

4 A large proportion, twenty-four per cent in this sample, of puerperal deaths are due to abortions and ectopic pregnancies. The inclusion of these deaths, while properly ascribed to conditions of pregnancy, in the maternal death rate is based on the number of

were more complete than those from attendants at home deliveries. Of the 9,278 hospital deliveries, data were obtained on 9,061, or 97.7 per cent, of the 3,369 home deliveries, reports were received on 2,719, or 78.4 per cent.

Methods of delivery

Table II shows the distribution of these deliveries according to place of delivery and method used.

From this table the following facts are observed:

1 22.1 per cent of all deliveries, or two of every nine are instrumental.

2 10.3 per cent, or slightly more than one tenth, are by major operative procedure.

3 7.2 per cent, or one in fourteen deliveries, are by version and extraction.

TABLE IV—PUERPERAL MORTALITY RELIABILITIES OF DIFFERENCES IN RATES RELIABILITIES EXPRESSED AS RATIO OF SUCH DIFFERENCES TO THEIR STANDARD RATES

	Normal Spontaneous	Low Forceps	Version
Low Forceps	0.79		
Version	2.30	3.08	
Cesarean	5.53	5.59	4.53

Reliabilities not computed for mid and high forceps deliveries and for breech presentations on account of unreliabilities of rates.

4 3.1 per cent, or one in every thirty three deliveries, are by cesarean section.

5 Significantly more of the instrumental and operative deliveries occur in the hospitals of the city than at home. The lone exception to this rule is in the case of the high forceps deliveries, where the slight difference is not statistically significant. The number of cases of this type of delivery is relatively so small, however (six per thousand births) that this method does not appear as a major problem. The figures seem to indicate that it is only used in Buffalo as an emergency procedure, and that the number of such emergency uses is relatively constant in home and hospital practice.

6 There is no difference between the relative numbers of breech and other faulty presentations found in home and hospital practice. The slight differences appearing are not significant, should these proportions remain constant for a much larger number of cases, the differences would, however, become real.

7 The numbers and percentages of this table are for the delivery methods only. For all variations from the normal there are undoubtedly good and sufficient reasons, (at least in the opinion of those attending the delivery. What these reasons may be we have no means of knowing.) To determine, for example, whether the per cent of deliveries by cesarean

TABLE V—STILL-BIRTHS AND NEONATAL DEATHS (UNDER ONE MONTH)—BUFFALO, JUNE 1, 1935, TO AUGUST 31, 1936, INCLUSIVE, CLASSIFIED ACCORDING TO METHODS OF DELIVERY. NEONATAL DEATH RATES PER 1,000 LIVE BIRTHS

Conclusions

Puerperal and neonatal mortality are without doubt closely associated with variations in obstetrical techniques. In general, the major operative procedures are highly correlated with increases in these mortality rates. However, the statistical study of such methods is insufficient in and of itself to draw absolute conclusions. There is need for a similar analysis of complicating factors of pregnancy in a large unselected group in order to clarify the true meaning of the differences in rates for the various methods.

The Subcommittee on Obstetrical Nursing of which Mrs. Anne L. Hanson, R.N., was chairman, presented its first report in April 1936. This report was compiled from information obtained from questionnaires sent to hospitals taking obstetrical cases. The report follows:

The Subcommittee on Obstetrical Nursing had a number of meetings and sent out three questionnaires to each institution in Erie County where maternity patients are cared for, namely fourteen. A summary of the questionnaires presents a fairly good picture of the type or service rendered maternity patients in this area.

The answers to the questionnaire submitted allowed the Committee to make the following report:

Prenatal. Twelve institutions have Prenatal Clinics but only two have field nursing service, and one has a tie-up with the Visiting Nursing Association.

Only eight institutions state they give a complete physical examination to the patient and when abnormal conditions are found, seven state patient is referred to the general clinic. Other institutions refer the patient to doctor or hospital or for home treatment but do not state who cares for the home treatment.

Some institutions report the taking of a prenatal history and of these five state they do not require complete report if a private physician is in charge of the case.

Eleven out of the fourteen institutions take a routine blood test, and ten "smears."

It is apparent that building arrangements in the Maternity Departments are certainly up to the average, if not above the average of some other cities. All have nurseries where babies are segregated in a unit apart from the mother, and all have special "Delivery Rooms." Fifty per cent of the institutions unfortunately have no "Preparation Rooms" and only seventy-five per cent have "Labor Rooms." Another unfortunate condition is that not all have isolation rooms when necessary for mother and baby.

The maternity nurses have been given good equipment by the hospitals. In only two hospitals must the mother's equipment be "shared," all the other institutions have individual equipment for the mother. In these same two institutions the baby's equipment is "shared" and in other institutions the baby has individual equipment.

Only one institution reports a "cubicle system" and one institution reports the nursery located in another part of the institution than the "Obstetrical Unit." On the whole it appears, from answers to questionnaires, that the equipment for the babies is not on as high a scale as that for the mothers.

TABLE VI—NEONATAL MORTALITY RELIABILITIES IN DIFFERENCES OF RATE. SEE TABLE IV 'BREECH' AND 'OTHERS' COMBINED WITH GROUP ONE

	Normal Spontaneous	Low Forceps	Mid	High	Ver-	Cesar-
					tion	ean
Low Forceps	1 38					
Mid	0 67	1 22

Version	3 04	3 39	1 51	1 56		
Cesarean	3 25	3 57	2 45	0 99	1 42	
Breech and Others	5 66	5 89	4 87	0 33	4 06	2 51

Nursing personnel. The number of supervisors, graduates, and students on duty in the Maternity Department differs in every institution. The Committee feels that the greatest weakness of the whole service is in the uneven distribution of personnel. Some institutions have the same number of nurses on duty at night as in the daytime, but as a general rule the number caring for patients at night is less. A summary of the figures gives us the following:

In Delivery and Preparation Rooms

- 2 supervisors less than in daytime
- 4 graduates less than in daytime.
- 2 students less than in daytime

In Postpartum Care

- 4 supervisors less than in daytime
- 18 graduates less than in daytime
- 20 students less than in daytime

In the Nursery

- 1 supervisor less than in daytime.
- 10 graduates less than in daytime.
- 7 students less than in daytime.

(Two institutions report one more student on duty at night.)

It is interesting to note that eleven institutions provide special nursing staff for care of babies. The remainder made no reply to the question.

Ward helpers. The Committee desires to draw attention to the fact that a number of institutions report no "ward helpers." It is the be-

deliveries of the viable products of conception. The total number of pregnancies in the population considered is an unknown quantity. To get an adequate picture of the postabortion death rate, it would be necessary to know the total number of abortions, both spontaneous and induced. Without such information, it is impossible to determine whether or not abortion is more important as a cause of death than is child-birth. Very little research has been done in this field.

Neonatal Mortality

Table V presents the classification of stillbirths and neonatal deaths, i.e., deaths under one month of age, according to method and place of delivery. Rates are given for the latter, but were not computed for the former.

It is true that figures for stillbirths show significant differences in the rates for certain of the methods reported. To obtain a picture of this relation it is necessary to separate these births into two groups: those in which the fetus died before the onset of labor, and those where death occurred during labor. Such a separation reduces the figures presented to such an extent that the various rates obtained lack reliability. Moreover, a study of a small sample of still-birth certificates showed that in the larger proportion of these, death was reported as having occurred before labor began. The data for stillbirths are therefore presented to show that there may be some connection with methods of delivery, and also to give the correction for the figures in Table II whereby to compute the rates for the neonatal mortality.

The data for neonatal mortality are shown according to the same scheme as that used in presenting those for puerperal mortality. In computing the Standard Errors of these rates, the same assumptions are made as heretofore. It is noticeable that when considering these deaths, the rates in all cases are more than twice their Standard Errors, and hence may be considered significant.

In Table VI the reliabilities of the differences in the neonatal mortality rates are shown, calculated in the same manner as those of Table IV. For these comparisons the deliveries reported as "Breech" and as "Others" are combined, notwithstanding, that the individual rates are both highly significant. Since most of the "Others" are cases of various abnormal presentations, the problem presented by them is closely related to that of the breech cases.

A consideration of the data of Tables V and VI leads to the following conclusions:

1 The lowest neonatal mortality rates are

those delivered normally and by low forceps, the highest, as is perhaps to be expected, are the breech and other faulty presentations.

2 There is no significant difference in rates between normal and low or midforceps deliveries, moreover, normal and low forceps deliveries show significantly lower rates than any other methods, the rates following faulty presentations are significantly higher than any others excepting those following cesarean sections.

3 Neonatal mortality rates following version deliveries are significantly higher than those following normal and low forceps deliveries, those following cesarean sections are significantly higher than those following normal, or low or midforceps deliveries.

4 In general, major operative techniques lead to a significantly greater chance of immediate death to the offspring than do normal and simpler instrumental techniques, while the chances of survival of misplaced fetuses are the smallest of all.

5 According to the most recent figures, from forty to sixty per cent of the infant mortality (deaths during the first year of life) occurs during the first month. During the past quarter century there has been a marked reduction in the infant mortality rate, but the greater part of this reduction has occurred in the deaths after one month. The reduction in the neonatal mortality rate has been relatively much less.

The infant deaths may be conveniently classified under three general heads:

(a) *Postnatal environmental conditions* The greater part of these are caused by preventable diseases. The control of this factor, especially in the virtual elimination of certain communicable diseases, has been especially important in reducing the infant mortality rate.

(b) *Congenital conditions* These are chiefly congenital malformations and premature births, and the death of the child occurs during the first month of life. The control of these causes is much more involved than is either of the other groups.

(c) *Conditions of birth* These are essentially an obstetrical problem.

The deaths considered here are, in more than ninety per cent of the cases, due to congenital conditions or to conditions at birth. In so far as the latter is the primary condition, the facts presented in this study may shed light on the problem of neonatal mortality, for those deaths due primarily to congenital conditions, these variations in method may or may not be significant. Again, further research on the primary causes of these neonatal deaths is important, in order accurately to gauge the true import of such facts as those presented here.

nurse being the contact between the physician and his patient and working under his direction, reporting to him exclusively

(b) *Clinic care for the indigent* Patients may attend clinic who plan to be delivered in their home, if referred by private physician. Patients unable to employ private physician should be urged to report at the Antepartum Clinic in the hospital where they plan to be delivered.

This recommendation is made to discourage patients from "shopping around" at various clinics. The field nurse servicing the clinic patient follows the orders of the clinic physician, carries out instructions regarding time for return visit, and gives the usual lessons in maternity hygiene.

Special consideration should be given to the obstetrical clinic patient that her full needs may be met when she attends the clinic, to avoid overexertion which is considered injurious by obstetricians. For example, provision made for treatment of cardiacs, diabetics, syphilitics, etc., during antepartum clinic visit. (This would apply also to postnatal clinic, especially emphasizing need for mother and baby being cared for at same clinic.)

Delivery in home Together with expert medical care, every woman is entitled to efficient nursing service.

If private nurse is not employed, services are available through Public Health Associations. The nurse who is engaged for the delivery period is responsible under the direction of the physician for instructing patient and family in every detail for the labor period.

Institutions

Admission—Through Delivery Special ward for patients not in actual labor when admitted.

Patients in labor admitted to labor room until physician orders transfer to delivery room.

Personnel It is desirable that the nurse, who makes the first contact with the patient, continue through labor and delivery. It is suggested that the personnel of the Obstetrical Department be considered as a separate unit under a properly prepared supervisor.

It is recommended that through the period of labor, there be one nurse to each patient and that the delivery room be serviced with not less than three nurses, at least one of whom should be a graduate.

The Committee believes that it would not deter from efficiency and would help in distribution of personnel if stirrups could be available for use.

Student nurses should not be considered observers only, but be made familiar with the actual process of labor and delivery. They

should receive instructions from the obstetrician regarding their method of procedure in an emergency.

POSTPARTUM CARE

(a) Continuous observation of normal cases for one hour. Pulse recorded at least every fifteen minutes. Emphasis laid for symptoms of shock or hemorrhage.

(b) In routine care of mother there should be one nurse for every four to five patients during day, one nurse for every eight to ten patients during night.

POSTNATAL CARE

(a) Nursery for new born infants staffed by special nursery supervisor with sufficient assistance to carefully supervise and care for each infant and to encourage breast feeding.

(b) It is desirable that each infant have individual equipment.

(c) Provision must be made for isolation when necessary.

(d) Special provision must be made for premature infants.

(e) All persons working in the nursery (including maids) should wear surgical gown, cap, and mask (after proper instruction regarding mask).

(f) Routine for nurses must include medical asepsis.

(g) No visitors allowed in nursery. Visitors to mother limited to minimum both in number and length of stay.

EDUCATION

(a) All graduates and students should attend and benefit by morning conferences and bedside clinics.

(b) Since every graduate nurse is a potential teacher, graduates on floor of obstetrical department must be under obligation to avail themselves of every opportunity for advancement through local institutes or postgraduate courses.

(c) In addition to requirements laid down by the Department of Education for classroom teaching and demonstration, provision should be made for adequate teaching at the bedside for every student nurse.

(d) A school of nursing should utilize every opportunity for teaching the students all of the intricacies of obstetrical procedures in order that they may be better equipped to meet emergencies which may occur during their professional life.

(e) Instruction to mothers should extend over entire period and include (1) practical demonstrations in bathing the baby, use and preparation of baby's tray, type of layette, preparation and care of breast tray, expression of breast milk, (2) lesson in health habits.

hef of the Committee that ward helpers are excellent for assisting nurses in doing duties that are not definitely professional

Instruction given to nurses The answers to the question regarding special instruction in technic and special observation of maternity were not very satisfactory. Some institutions answered that special instruction is given to both graduates and students but there was no indication of the type of instruction given. From others this question remained without reply.

The average number of mothers and babies cared for by—

(a) Supervisors 6 to 45

(b) Graduates 4 to 10

(c) Students 4 to 13

This shows there must be a great deal of variance in the type of care and supervision given patients in the institutions.

In reply to the question regarding length of time in which the mother and baby have continuous observation after delivery the institutions show a great variance of time. Some stated twenty-four hours, some stated one hour, others twelve hours, and others ten hours.

Student case work The replies to the questionnaire show that the student nurses averaged twenty "Delivery" cases. Six institutions stated that it is observation only. Only one institution gives any experience in "home deliveries."

Instructions to patient Postpartum examination is given by twelve institutions out of fourteen and differs in the date after delivery from one to six weeks.

Instruction in hygiene Care of the baby with demonstrations is given by eleven institutions.

Only one institution makes routine home calls by field nurses after the patient returns home.

It is apparent that home visits by nurses to prenatal cases is not general, and it is the opinion of the Committee that this constitutes a definite lack of care of maternity cases. The institutions are not availing themselves of the regular public health service given by various public health nursing agencies, which would be invaluable first to the patient and, second, to the hospital.

The hospitals generally do not seem to have taken advantage of all their opportunities to educate and instruct the mothers while they are still patients on their floors, at a time when the patient is most receptive and less burdened by other responsibilities and cares. Perhaps more organized instructions should be incorporated into the general plan during the whole period of hospitalization.

Summary

This Subcommittee suggests that

1 The Erie County Medical Society Committee on Maternity bring together nurse representatives of all institutions giving maternity care, and also representatives of the public health nursing agencies giving any form of maternity care in order that there be a better understanding of the work of the groups. It is suggested that this be not limited to registered nurse training schools but to all groups where maternity service is being rendered.

2 (a) That if necessary, an Obstetrician arrange for definite instruction in the physician's requirements in maternity nursing. (b) That a well-qualified obstetrical nurse give instruction in the technic of maternity nursing.

3 The Committee suggests that the Chairman of the Survey Committee meet with the group and outline a simple plan for discussion which will include the best methods of securing for patients in the County of Erie efficient prenatal, delivery, postpartum, and postnatal care.

4 *Education* (a) *Student Nurses*—It is recommended that the faculty of the schools of nursing study the new curriculum on maternity nursing which has been compiled by the National League of Nursing Education. It seems certain that this curriculum will be finally approved by the three National Nursing Organizations at the Biennial convention at Los Angeles in June 1938, and become the basis for all schools of nursing that are of a high standing. Whether a school is registered or not, the Committee believes the new curriculum should be used as a basis for student nurse education. (b) The Committee further recommends that all graduates employed by hospitals be given well prepared postgraduate education in maternity service either through lectures or institutes from time to time so that the service may be kept up to date.

In accordance with the foregoing recommendation No 3, a meeting of the head obstetrical nurses of the various institutions doing obstetrical nursing was called. A subcommittee was appointed to draw up an outline of Minimum Standards for Obstetrical Nursing. This sub-committee's report follows.

Minimum Standards for Nursing in Complete Maternity Cycle

Antepartum Every expectant mother is entitled to both medical and nursing care throughout the antepartum period.

The first objective of all field nurses is to secure medical care as early as possible for every prenatal patient.

(a) *Private physician* Field nurse service is available for every private physician, the

nurse being the contact between the physician and his patient and working under his direction, reporting to him exclusively

(b) *Clinic care for the indigent* Patients may attend clinic who plan to be delivered in their home, if referred by private physician. Patients unable to employ private physician should be urged to report at the Antepartum Clinic in the hospital where they plan to be delivered.

This recommendation is made to discourage patients from "shopping around" at various clinics. The field nurse servicing the clinic patient follows the orders of the clinic physician, carries out instructions regarding time for return visit, and gives the usual lessons in maternity hygiene.

Special consideration should be given to the obstetrical clinic patient that her full needs may be met when she attends the clinic, to avoid overexertion which is considered injurious by obstetricians. For example, provision made for treatment of cardiacs, diabetics, syphilitics, etc., during antepartum clinic visit. (This would apply also to postnatal clinic, especially emphasizing need for mother and baby being cared for at same clinic.)

Delivery in home Together with expert medical care, every woman is entitled to efficient nursing service.

If private nurse is not employed, services are available through Public Health Associations. The nurse who is engaged for the delivery period is responsible under the direction of the physician for instructing patient and family in every detail for the labor period.

Institutions

Admission—Through Delivery Special ward for patients not in actual labor when admitted.

Patients in labor admitted to labor room until physician orders transfer to delivery room.

Personnel It is desirable that the nurse, who makes the first contact with the patient, continue through labor and delivery. It is suggested that the personnel of the Obstetrical Department be considered as a separate unit under a properly prepared supervisor.

It is recommended that through the period of labor, there be one nurse to each patient and that the delivery room be serviced with not less than three nurses, at least one of whom should be a graduate.

The Committee believes that it would not deter from efficiency and would help in distribution of personnel if stirrups could be available for use.

Student nurses should not be considered observers only, but be made familiar with the actual process of labor and delivery. They

should receive instructions from the obstetrician regarding their method of procedure in an emergency.

POSTPARTUM CARE

(a) Continuous observation of normal cases for one hour. Pulse recorded at least every fifteen minutes. Emphasis laid for symptoms of shock or hemorrhage.

(b) In routine care of mother there should be one nurse for every four to five patients during day, one nurse for every eight to ten patients during night.

POSTNATAL CARE

(a) Nursery for new born infants staffed by special nursery supervisor with sufficient assistance to carefully supervise and care for each infant and to encourage breast feeding.

(b) It is desirable that each infant have individual equipment.

(c) Provision must be made for isolation when necessary.

(d) Special provision must be made for premature infants.

(e) All persons working in the nursery (including maids) should wear surgical gown, cap, and mask (after proper instruction regarding mask).

(f) Routine for nurses must include medical asepsis.

(g) No visitors allowed in nursery. Visitors to mother limited to minimum both in number and length of stay.

EDUCATION

(a) All graduates and students should attend and benefit by morning bedside clinics.

(b) Since every graduate nurse is a potential teacher, graduates on floor of obstetrical department must be under obligation to avail themselves of every opportunity for advancement through local institutes or postgraduate courses.

(c) In addition to requirements laid down by the Department of Education for classroom teaching and demonstration, provision should be made for adequate teaching at the bedside for every student nurse.

(d) A school of nursing should utilize every opportunity for teaching the students all of the intricacies of obstetrical procedures in order that they may be better equipped to meet emergencies which may occur during their professional life.

(e) Instruction to mothers should extend over entire period and include (1) practical demonstrations in bathing the baby, use and preparation of baby's tray, type of layette, preparation and care of breast tray, expression of breast milk, (2) lesson in health habits.

hief of the Committee that ward helpers are excellent for assisting nurses in doing duties that are not definitely professional

Instruction given to nurses The answers to the question regarding special instruction in technic and special observation of maternity were not very satisfactory. Some institutions answered that special instruction is given to both graduates and students but there was no indication of the type of instruction given. From others this question remained without reply.

The average number of mothers and babies cared for by—

(a) Supervisors 6 to 45

(b) Graduates 4 to 10

(c) Students 4 to 13

This shows there must be a great deal of variance in the type of care and supervision given patients in the institutions.

In reply to the question regarding length of time in which the mother and baby have continuous observation after delivery the institutions show a great variance of time. Some stated twenty-four hours, some stated one hour, others twelve hours, and others ten hours.

Student case work The replies to the questionnaire show that the student nurses averaged twenty "Delivery" cases. Six institutions stated that it is observation only. Only one institution gives any experience in "home deliveries."

Instructions to patient Postpartum examination is given by twelve institutions out of fourteen and differs in the date after delivery from one to six weeks.

Instruction in hygiene Care of the baby with demonstrations is given by eleven institutions.

Only one institution makes routine home calls by field nurses after the patient returns home.

It is apparent that home visits by nurses to prenatal cases is not general, and it is the opinion of the Committee that this constitutes a definite lack of care of maternity cases. The institutions are not availing themselves of the regular public health service given by various public health nursing agencies, which would be invaluable first to the patient and, second, to the hospital.

The hospitals generally do not seem to have taken advantage of all their opportunities to educate and instruct the mothers while they are still patients on their floors, at a time when the patient is most receptive and less burdened by other responsibilities and cares. Perhaps more organized instructions should be incorporated into the general plan during the whole period of hospitalization.

Summary

This Subcommittee suggests that

1 The Erie County Medical Society Committee on Maternity bring together nurse representatives of all institutions giving maternity care, and also representatives of the public health nursing agencies giving any form of maternity care in order that there be a better understanding of the work of the groups. It is suggested that this be not limited to registered nurse training schools but to all groups where maternity service is being rendered.

2 (a) That if necessary, an Obstetrician arrange for definite instruction in the physician's requirements in maternity nursing. (b) That a well-qualified obstetrical nurse give instruction in the technic of maternity nursing.

3 The Committee suggests that the Chairman of the Survey Committee meet with the group and outline a simple plan for discussion which will include the best methods of securing for patients in the County of Erie efficient prenatal, delivery, postpartum, and post-natal care.

4 *Education* (a) *Student Nurses*—It is recommended that the faculty of the schools of nursing study the new curriculum on maternity nursing which has been compiled by the National League of Nursing Education. It seems certain that this curriculum will be finally approved by the three National Nursing Organizations at the Biennial convention at Los Angeles in June 1938, and become the basis for all schools of nursing that are of a high standing. Whether a school is registered or not, the Committee believes the new curriculum should be used as a basis for student nurse education. (b) The Committee further recommends that all graduates employed by hospitals be given well prepared postgraduate education in maternity service either through lectures or institutes from time to time so that the service may be kept up to date.

In accordance with the foregoing recommendation No 3, a meeting of the head obstetrical nurses of the various institutions doing obstetrical nursing was called. A subcommittee was appointed to draw up an outline of Minimum Standards for Obstetrical Nursing. This sub-committee's report follows.

Minimum Standards for Nursing in Complete Maternity Cycle

Antepartum Every expectant mother is entitled to both medical and nursing care throughout the antepartum period.

The first objective of all field nurses is to secure medical care as early as possible for every prenatal patient.

(a) *Private physician* Field nurse service is available for every private physician, the

nurse being the contact between the physician and his patient and working under his direction, reporting to him exclusively

(b) *Clinic care for the indigent* Patients may attend clinic who plan to be delivered in their home, if referred by private physician. Patients unable to employ private physician should be urged to report at the Antepartum Clinic in the hospital where they plan to be delivered

This recommendation is made to discourage patients from "shopping around" at various clinics. The field nurse servicing the clinic patient follows the orders of the clinic physician, carries out instructions regarding time for return visit, and gives the usual lessons in maternity hygiene.

Special consideration should be given to the obstetrical clinic patient that her full needs may be met when she attends the clinic, to avoid overexertion which is considered injurious by obstetricians. For example, provision made for treatment of cardiacs, diabetics, syphilitics, etc., during antepartum clinic visit. (This would apply also to postnatal clinic, especially emphasizing need for mother and baby being cared for at same clinic.)

Delivery in home Together with expert medical care, every woman is entitled to efficient nursing service.

If private nurse is not employed, services are available through Public Health Associations. The nurse who is engaged for the delivery period is responsible under the direction of the physician for instructing patient and family in every detail for the labor period

Institutions

Admission—Through Delivery Special ward for patients not in actual labor when admitted.

Patients in labor admitted to labor room until physician orders transfer to delivery room.

Personnel It is desirable that the nurse, who makes the first contact with the patient, continue through labor and delivery. It is suggested that the personnel of the Obstetrical Department be considered as a separate unit under a properly prepared supervisor.

It is recommended that through the period of labor, there be one nurse to each patient and that the delivery room be serviced with not less than three nurses, at least one of whom should be a graduate.

The Committee believes that it would not deter from efficiency and would help in distribution of personnel if stirrups could be available for use.

Student nurses should not be considered observers only, but be made familiar with the actual process of labor and delivery. They

should receive instructions from the obstetrician regarding their method of procedure in an emergency

POSTPARTUM CARE

(a) Continuous observation of normal cases for one hour. Pulse recorded at least every fifteen minutes. Emphasis laid for symptoms of shock or hemorrhage.

(b) In routine care of mother there should be one nurse for every four to five patients during day, one nurse for every eight to ten patients during night.

POSTNATAL CARE

(a) Nursery for new born infants staffed by special nursery supervisor with sufficient assistance to carefully supervise and care for each infant and to encourage breast feeding

(b) It is desirable that each infant have individual equipment.

(c) Provision must be made for isolation when necessary

(d) Special provision must be made for premature infants

(e) All persons working in the nursery (including maids) should wear surgical gown, cap, and mask (after proper instruction regarding mask)

(f) Routine for nurses must include medical asepsis

(g) No visitors allowed in nursery. Visitors to mother limited to minimum both in number and length of stay

EDUCATION

(a) All graduates and students should attend and benefit by morning conferences and bedside clinics

(b) Since every graduate nurse is a potential teacher, graduates on floor of obstetrical department must be under obligation to avail themselves of every opportunity for advancement through local institutes or postgraduate courses

(c) In addition to requirements laid down by the Department of Education for classroom teaching and demonstration, provision should be made for adequate teaching at the bedside for every student nurse

(d) A school of nursing should utilize every opportunity for teaching the students all of the intricacies of obstetrical procedures in order that they may be better equipped to meet emergencies which may occur during their professional life.

(e) Instruction to mothers should extend over entire period and include (1) practical demonstrations in bathing the baby, use and preparation of baby's tray, type of layette, preparation and care of breast tray, expression of breast milk, (2) lesson in health habits

HOME CARE

Before discharge, provision must be made for home care through (1) Outpatient department field service, (2) Affiliation with public health agency (service available for both private physicians' home cases and hospital)

FOLLOW-UP FIELD SERVICE

Objectives of nursing visits include (1) To encourage return of mother and baby to private physician or hospital clinic. (2) Observe mother and baby and report any apparent abnormal condition to doctor. (3) Teach and demonstrate good health habits and prevention of disease

The Obstetrical Study Group, of which Dr. Goldsborough acted as Chairman, submitted the results of its study in a series of charts (Tables VII-X, and from which Charts III-V have been prepared) prefaced by the following comment

Herewith is presented the detailed analysis of maternal deaths in Erie County in 1935. A short summary covering 1935 and 1936 is included. From the study we have confirmed our conclusions of 1935, foremost in importance is the serious nature of operative obstetrics, especially cesarean sections. Sections constituted three per cent of all deliveries in Erie County, which means that one-third of all the deaths occurred in three per cent of the deliveries.

Puerperal sepsis in both years constituted the largest single cause in all deliveries but was highest in cesarean sections. Infection, theoretically is preventable but practically it is not. However, constant vigil and care and improvement of technic should lead to its reduction.

As to the preventability of deaths the committee was unable to come to definite conclusions upon whom to place the responsibility. In many instances poor judgment in the choice of procedures used could be criticised.

In the deaths from toxemia all were due to lack of prenatal care.

The committee was handicapped seriously in its study because of the lack of postmortem examinations. Many of the deaths were under the control of the medical examiner and in practically every instance no autopsy was performed. Many cases in which questionable diagnoses were made could have been definitely diagnosed with the cooperation of the medical examiner. The committee urges the Erie County Medical Society to take a more definite stand on this point.

In many instances, after careful study and much discussion regarding the diagnosis and

cause of death we were amazed to find distinctly incorrect causes of death upon the certificate. For instance, in one case, a patient dying from peritonitis had as a contributory cause "post-puerperal seven years." In investigating this case the physician explained that his patient had had an infected abortion seven years previous and her death was due to a lighting-up of the old infection. He had overlooked a long-standing complete prolapse as the most probable cause. This death certificate was accepted by the authorities. If the certificates continue to be filed without investigation we can see no particular use for

Department of Health records, as they do not represent the accurate state of affairs. Every certificate should be a privileged communication so that true statements will not lead to public exposure with the possibility of legal suit.

As a result of a study of all of the foregoing statistics, analyses, data and reports, the Maternal Mortality Survey Committee of the County of Erie has formulated certain conclusions and recommendations which are hereby submitted.

The tables "Types of Delivery and

Causes of Maternal Deaths" for the calendar years 1935 and 1936 prepared by the Obstetrical Study Group (Tables VII-XI), tabulate 126 deaths as being unquestionably puerperal. If from this number are excluded deaths occurring after normal (spontaneous) deliveries, abortions, extrauterine pregnancies and undelivered cases, there remain sixty-six deaths which must be classified as following operative deliveries. Cesarean section preceded thirty-nine, or fifty-nine per cent, of these. In upstate New York in 1932, deaths following cesarean section comprised thirty-six per cent of all maternal deaths after operative procedures.

The statistical analysis of Tables II and III points out that, in general the chances of death are significantly greater when artificial technic are used than when deliveries are normal (spontaneous) or technics are simpler. The tables in this series show that the most common types of delivery are spontaneous, forceps, version, and cesarean section. Of these, spontaneous and forceps delivery show such a comparatively low mortality that they need not be considered as important in the production of our high maternal mortality rate.

The analysis clearly demonstrates that the most significant field of danger lies in delivery by (1) cesarean section (2) version and extraction. So a definite attack on our maternal mortality rate must logically begin by considering delivery by these procedures. The critical ratio for cesarean section compared to spontaneous delivery is 5.53* (Table IV).

In the Report of the New York Academy of Medicine, page 137, we read "the incidence of cesarian section in the hospitals of the city is seen to be high, 2.2% of all deliveries. This extremely high incidence in the series is a matter of concern."

In Erie County the hospital incidence

* "It has been practically a universal custom among biometric workers to say that a difference which is smaller than twice its probable error is probably not significant, whereas a difference which is three or more times its probable error is either 'certainly,' or at least 'almost certainly,' significant."—Page 214, "Introduction to Medical Biometry and Statistics" by Raymond Pearl, W. B. Saunders, 1923

of cesarean section for the period of our study was 43 per cent, almost double that of New York City. Furthermore, 31 per cent of all deliveries in Erie County were by cesarean section, which is one in every thirty-three deliveries. The maternal mortality rate for spontaneous deliveries is 2%, while for cesarean section it is 7.5%.

Everyone recognizes, of course, that there are absolute indications calling for cesarean sections and in these instances it may be a life-saver. The operation, however, should be sharply limited to these indications because of the proven increased risk to the mother from this major surgical procedure.

The study so far, then, definitely demonstrates the need for re-examining the indications for cesarean section. Others have reached the same conclusion.

The Maternal Mortality study in fifteen states made by the United States Department of Labor contains this statement: "The tremendous mortality attending Cesarean sections throughout the United States warrants a careful review of the indications in the choice of operation."

Dr DeLee (*Year Book of Obstetrics and Gynecology*, page 265, 1934) states:

I must, however, warn against the growing misuse of a noble operation. The mortality from it in the United States is at least 6% which is frightful and something must be done about it.

Erie County rate was 7.5% for the period studied.

The New York Survey also states as a result of its studies, page 139:

The indications for the cesarean operation need restatement and further limitations to really valid causes, such as severe degrees of contraction of the pelvis. Sharp reduction in the cesarean sections performed is to be strongly recommended.

Dr Edwin G. Langrock in an article in this JOURNAL (36:383, 1936) says:

Cesarean section has a much higher mortality rate than we suppose even when the low cervical operation is done at the optimum time by the most skilled operator. It is evident that fewer cesarean sections should be performed, especially since far too many are being done for nonvalid indications.

Let us give patients solid conservative treatment. This is safe and satisfactory. Let us carry out intelligent, watchful expectancy in labor. Let us acquire experience and skill in vaginal delivery, and these two will give us the courage to treat our patients conservatively throughout labor and to deliver them through the natural passage.

We should disseminate to the laity through an extension of our public education program the fact that mechanized maternity is not synonymous with safety, that artificial procedures undertaken "merely to relieve pain or to shorten labor increase the risk to the mother," as has also been shown by all other surveys and studies to date.

The public's responsibility in this regard cannot be too greatly stressed, for all too often the physician is chosen by the prospective mother for his reputation for giving a "short" or "painless" delivery.

We must continue to stress our campaign for prenatal care until every prospective mother realizes not only what adequate prenatal care is, but also its importance to her health and safety.

As approximately twenty-five per cent of all maternal deaths follow abortions, it is strongly recommended that we continue and enlarge our campaign for public education against this dangerous procedure. We may best do this by continuing an active cooperation with the Child Health Week Committee, which, in cooperation with the County Society, has waged a spirited crusade against this evil. However, the committee recommends that it would be desirable in all studies of this kind to separate postpartum deaths from postabortion and extrauterine pregnancies. Until this is done, the figures are misleading and readily become the basis of misrepresentation in popularizations of the subject.

More postgraduate work in practical obstetrics should be made generally available by the County Society.

The committee also recommends a "sampling study" to be begun at once, on a series of several hundred consecutive births where the mother survives, using the revised form CB 122 United States Children's Bureau, Department of Labor, or an abridgment of it.

In order to carry out the recommendations that have been made in the foregoing section considerable organization of the available facilities will be necessary. Before presenting a plan for Erie County, a description of successful obstetric plans which have been developed in two other communities is presented at this point. The first, which appeared in the *NEW YORK STATE JOURNAL OF MEDICINE* in 1934, is a plan outlined for organized maternal welfare as developed in New Jersey.

ORGANIZED MATERNAL WELFARE WORK IN NEW JERSEY

ARTHUR W. BINGHAM, M.D.

Chairman, Maternal Welfare Committee, State Medical Society of New Jersey

Organized maternal welfare work in New Jersey was started in 1923 when the Medical Commission for Maternal Welfare of Essex County, consisting of twelve physicians, was appointed by the County Medical Society. Meetings were held each month at first but later every second month, the detail work being carried on by various committees, prenatal, hospital, educational, follow-up, statistical, and finance.

The prenatal committee organized prenatal work in every part of Essex County following largely the methods employed by the Maternity Center Association of New York City and the Maternity Center of the Oranges, which had been in operation for two years. Prenatal history cards were printed by the commission and distributed without cost to all physicians in the county who wished to use them.

The hospital committee checked up the work of the hospitals, inducing them to use similar record sheets so that the annual reports would be uniform. An obstetrical report is received each year by this committee from each of the leading hospitals in the county, a few small private hospitals not cooperating as yet. A summary of three years of these reports was published in the *American Journal of Obstetrics and Gynecology*. Directors of one hospital with sixty-six cesarean sections out of 900 deliveries and another hospital with forty-four sections out of 400 deliveries read these reports with the result that in 1933 there were only twenty-one sections in the former hospital and eleven in the latter.

The educational committee has attempted to present the idea of better obstetrics to the public as well as to the physicians. Many talks have been given by leading obstetricians and one year a drive for better obstetrics was conducted and an afternoon meeting for women was held.

The follow-up committee investigated every maternal death in Essex County by questionnaire at first, but during the past year a paid

investigator has made personal visits, using for reports the same blanks which were used in the survey by the New York Academy of Medicine.

The commission started its work in a small way, gradually developing during the past eleven years as the confidence of physicians has been gained. The work is financed by the Essex County Medical Society. During the existence of the Maternal Welfare Commission, the uncorrected maternal mortality for Essex County according to the State Board of Health has been reduced from 69 to 44 per 1,000 live-births and in Newark from 74 to 45 per 1,000 live-births.

As a result of this work in Essex County, a Maternal Welfare Committee was appointed by the State Medical Society two years ago, the object being to organize Maternal Welfare Commissions in every county. This has been accomplished in all but one county and we hope to interest this county before long. The work in some counties is much more advanced than in others, but each county has its problems, and time will be required to get the desired results.

The State Committee meets twice yearly with the members of the various commissions. Reports are heard from each county represented. There is also a talk by some prominent obstetrician. One meeting is held at the time of the State Society meeting at Atlantic City in June and the other in Newark in the winter. On the whole, there has been great interest shown and we have had excellent co-operation.

In New Jersey, much of the obstetrical work is done by general practitioners and any plan to improve obstetrics must include them. This is done by allowing them to attend cases in our best hospitals under supervision and subject to certain rules. At Orange Memorial Hospital, which takes emergency and ambulance cases as well as private cases, seventy general practitioners attended cases in 1933. There were 1,045 deliveries with three maternal deaths and only five cesarean sections. Physicians are expected to follow the regular hospital routines, and the following rules are posted in each delivery room:

Consultation with one of the obstetrical staff is required in all of the following cases:

- (a) All prolonged labors (24 hours),
- (b) Cases requiring cesarian sections,
- (c) Breech presentations (unless very premature),
- (d) Difficult forceps cases or versions,
- (e) Occiput posterior presentations requiring forceps or version,
- (f) Other complicated cases: eclampsia, placenta praevia, etc.

In some hospitals in the county the rules read "Consultation must be had with a qualified consultant," giving a little more choice.

If the general practitioners are not allowed to attend cases in our best hospitals, they are obliged to use the private nursing homes or keep the patient at home. In neither of these places do they have any supervision nor is it easy to get consultation without considerable

trouble and expense. In the supervised hospital, consultations can be promptly given without charge unless the patient is able to pay a moderate fee.

Therefore, we recommend a sufficient number of beds in Class A hospitals where the general practitioners as well as the obstetricians may take their patients, where their work may be supervised, and where they may have the advantage of consultation in abnormal cases.

The second successful plan is that of the Hospital Obstetric Society of Ohio, part of which is presented herewith verbatim.

HOSPITAL OBSTETRIC SOCIETY OF OHIO

Obstetric Recommendations for Group 1 Hospitals

The recommendations of the Hospital Obstetric Society of Ohio covering Group 1 hospitals were presented to the April 1935 convention of The Ohio Hospital Association and referred by the convention to the Committee on Professional Relations with power to act. These were considered by the Committee in conference with a committee of The Hospital Obstetric Society and after some revision they were approved. They now become the joint recommendation of both the Hospital Obstetric Society of Ohio and The Ohio Hospital Association for Group 1 hospitals, that is, those having 24 or more bassinets, or more than 300 deliveries per year. In the interest of better hospital obstetrics, The Ohio Hospital Association urges every hospital in this group to adopt these standards as rapidly as possible. The recommendations are as follows:

The Committee on "Organization and Standards" of the Hospital Obstetric Society of Ohio, in presenting this report, has been conscious of the economic and financial state of the Hospitals of Ohio, and has endeavored to avoid imposing unnecessary additional burdens. We do, however, request your wholehearted cooperation by rearranging, where necessary, existing structural facilities, and reorganizing the obstetric staff and nursing services to comply with our required standards. We are all aware of the unwarranted and unjust criticism hospital obstetrics has had to endure. Possibly some has been merited. It is our desire, with your cooperation, to so conduct the obstetrical department in our hospitals that the end results will disprove further unmerited comment. With whatever acumen, skill, energy and idealism we are endowed, we have dedicated ourselves to the task of making motherhood safe in our Ohio hospitals.

1. There should be in each hospital a definite organization of the obstetric staff, with a director and associates, senior attending, junior attending physicians, residents and internes—

all elected for ability, not popularity. There may be a courtesy staff. The Director of Obstetrics should be an F.A.C.S. or diplomat of the Board of Obstetrics and Gynecology.

There must be definite periods of service. Residents should not and internes shall not serve in other departments when on obstetric service. This requirement will necessarily be modified for Group 2 and 3 Hospitals, but not to impair the observance of a rigid obstetrical technique.

The Director shall be responsible for the medical conduct of the department and shall formulate all rules and regulations, with power to enforce, governing the operation of the department, in cooperation with the hospital administration.

Each hospital shall secure the signature of each physician having the privilege of obstetrics in that hospital to the following pledge:

I, the undersigned member of the Courtesy Obstetric Staff of _____ Hospital hereby agree:

(1) That the care of each of my patients admitted to the Obstetric Division of _____ Hospital, shall be subject to intervention, supervision and control by the Director of Obstetrics or his chosen representative, whenever in the judgment of the Director such intervention, supervision or control is advisable for the welfare of the patient.

(2) That I will attend the regular conferences, clinics and meetings of the staff as requested by the Obstetric Director.

(3) That I will make all reasonable effort to improve my knowledge of obstetrics and skill in its practice.

(4) That I will be subject to and will conform with such other rules and regulations as shall from time to time be made by the Hospital for the good of the service or the benefit of the patient.

(Date) _____ (signed) _____

Where major obstetric procedures are indicated, that is, any interference in a case where the presenting part is not engaged, authority must be obtained from the Director of Obstetrics or his authorized representative.

The Director and active staff shall formulate a routine obstetric technique ante-, intra-, post-partum, to which all physicians attending an obstetric case must subscribe and be rigidly controlled by the Director of the Department, so that there shall be neither omissions nor supplemental procedures instituted. Residents and internes under no condition, shall serve in the capacity of consultant or perform a major obstetric procedure at the request of any physician attending a private obstetric case.

(2) Records shall consist of suggested forms attached—ante-partum, intra-partum, progress notes, bedside notes, laboratory and pathological record. All records shall be completed at time of the patient's discharge, and transferred to record librarian and record committee of the staff for checking and classification before permanent filing. Case records shall be available to the staff for statistical study. Exactness is urged as these records are of statistical value only when correctly complete.

(3) There should be adequate laboratory facilities available to the obstetric department, chemical, bacteriological, serological, pathological, X-ray, metabolism, cardiology, and if possible photographic.

There shall be weekly, bi-weekly or monthly conferences of the obstetric staff, at which the clinical work of the department shall be reviewed and discussed.

Special attention is to be paid to mortality, morbidity, still-birth, infections and complications of labor.

(4) The Hospitals' Obstetric Department should provide for patient occupancy in a single unit of space, not interrupted by space used for any other purpose. It should be a compact unit, containing the following facilities, the private room, semi-private room (2 beds) wards, private or free, not to exceed four (4) beds each. In semi-private and four (4) bed wards, some provision for privacy should be provided by screening in some manner, movable or permanent, as will be most feasible in the hospital set up. No other type of patient shall be placed in the obstetrical division. Provision for isolation, for infected cases, is mandatory, preferably in single room with running water and individual nursing facilities. There should be an isolation unit in each nursery or a separate nursery with cubicle arrangement to which any baby developing a skin rash, temperature or infection can be transferred. The general nursery should be sound-proofed and so situated, as not to annoy the mothers. Bathing facilities should be adequate, and there should be self-contained nursing facilities with service rooms. The general nursery should not be in close proximity to the labor or delivery rooms. There should be individual cribs, so placed that there is sufficient space between cribs, that nursing service will not be impaired. The delivery suite should have labor or pre-delivery rooms one for each 15 patient beds, each accommodating only one patient. The labor rooms should have their separate service room, fully equipped for nursing service. There should be one delivery room for each 25 patient beds. In construction and equipment they should be comparable to the standard operating room and should have a service room equipped with sterilizing facilities, instruments and water, warming units for blankets, linens and solutions, instrument and waste sinks.

Dressing, gowns, etc., should, preferably, be requisitioned from the central supply station. There should not be more than one delivery table in the delivery room so that rigid surgical technique can be maintained. The labor and delivery rooms should be a self-contained, separate unit, so situated that there may be some degree of isolation to minimize noise, confusion and disturbance to patient occupancy. Most important for isolation is the maintenance of rigid aseptic technique to minimize cross infection. The entire obstetrical department shall be under the supervision of a graduate nurse preferably one who has had post-graduate training in obstetrics, and endowed with executive ability. The delivery room nursing personnel should be trained in obstetric procedure and should not serve in the surgical department, in order that cross infections be avoided. Detailed obstetrical and nursing procedures, including anaesthesia have been purposely

omitted, except that under no circumstances should nurses serving on the obstetric division, be permitted to contact patients on any other service, nor shall nurses from other divisions, circulating nurses, etc., be called upon to serve in the maternity division. These procedures should be set up in the hospital house rules and regulations.

(5) Almost all hospitals are characterized by the spirit we call "Personality," reflecting the enthusiasm, idealism and progressiveness of their medical, administrative, and nursing staffs. This spirit should be encouraged, for it has always been the "force" stimulating us to greater achievement. We appreciate that rigid standardization negatives this "spirit" and in a large measure creates human automatons. The standards we present in this report are in the nature of a statement of principles, and we look to the initiative of each institution for the development of methods, which are appropriate to its individual requirements and which have been found by trial and experience to be the safest and most effective in restoring the patient to her previous natural life. The executive committee of the Hospital Obstetric Society of Ohio was afforded the privilege of reviewing that most excellent and comprehensive "Manual of Maternity Care" prior to its presentation to The American Hospital Association by Dr. Buerki at the Philadelphia meeting. We recommend this manual to you as a guide in formulating your respective house rules and regulations, as it embodies the accepted principles and procedures, both staff and administrative, essential in conducting the efficient operation of a Hospital Obstetric Division.

As a matter of fact, one large hospital in Buffalo has already begun to act along the lines indicated in the above reports. On March 25, 1937, the president of its medical staff sent letters to members of its staff containing this paragraph:

All physicians attending obstetrical patients in this hospital shall be requested to call a consultant, either from the Attending or the Assistant Attending Obstetrical Staff of this hospital, or from the Attending Obstetrical Staff of any other approved hospital, in all abnormal cases and before they may undertake in this hospital, any operation of greater extent than low forceps delivery.

The Maternal Mortality Survey Committee, County of Erie, proposes the following obstetric plan for the County of Erie.

The Special Maternal Mortality Sur-

vey Committee shall be dissolved and replaced at once by a permanent committee to be known as the "Obstetric Council of the Medical Society, County of Erie."

This Council shall function as follows:

1 *Organization* The Medical Society, County of Erie, shall request each hospital taking obstetrical cases to appoint a representative from its obstetric staff (representative is to be a member of the Medical Society, County of Erie) to the Obstetric Council of the Medical Society of the County of Erie. This group shall organize and elect officers and proceed to carry out.

2 *The Purposes of the Obstetric Council* This Council shall carry on the statistical and educational work of the survey (Ex "sampling study" mentioned above), working generally towards the goal of a lowered puerperal mortality rate and the general improvement of obstetric practice.

3 *Education of the Public* This shall continue in cooperation with the Child Health Week Committee and with other recognized public agencies. This education is to stress particularly minimum accepted standards of prenatal, delivery, and postnatal service by physicians and nurses both in institutions and in homes. Stress is also to be laid upon the public's responsibility.

4 The Council shall stand as a source of authoritative information on obstetrics to the social agencies and to the community at large.

5 The Council shall promote free and open staff discussions in the individual hospitals, to develop better hospitalization methods, to study all conditions which affect the welfare of obstetric patients and to introduce and maintain standard approved obstetric technique in all the institutions of the city.

6 The Survey Committee finally recommends that this report be published at once and that each member of the Medical Society be furnished with a copy.

925 DELAWARE AVE.

Two members of the state legislature, Senator Thomas C. Desmond, of Newburgh, and Assemblyman Charles H. Breit-

bart, of Brooklyn, have announced that they will introduce new premarriage medical examination bills at the next session.

DIFFERENTIATION BETWEEN RECEDING AND PROGRESSING CASES OF PETROSITIS

RALPH ALMOUR, M D, F A C S, *New York City*

From the Otolaryngological Department, Beth Israel Hospital

Before proceeding to the discussion of what factors distinguish the progressing from the receding cases of petrositis, it is necessary to review in brief the basic symptomatology of this disease. The clinical picture is composed of general signs and symptoms, and localizing or focal signs. The former comprise homolateral pain distributed along the first branch of the fifth nerve, usually intra- or supraorbital, narrowing of the palpebral fissure on the affected side, recurring or continuing tympanomastoidal purulency, and a low grade sepsis. The latter, the localizing signs, embrace evidences of involvement of the sixth, seventh, ninth, tenth, and eleventh nerves, vertigo, nystagmus, nausea, and vomiting of a transitory nature. To all these should be added the roentgenological findings.

The basic picture of eye-pain, recurrent or continuing otorrhea, narrowing of the palpebral fissure, and low grade sepsis still stand as our best diagnostic aid. True, a septic type of temperature not always is present in sinus thrombosis, nor is pain or tenderness always present in acute surgical mastoiditis, but these phenomena are considered the ordinary or common ones from which all departures are considered uncommon. For these departures, however, there are definite explanations, and so when present, do not handicap one in the diagnosis of this disease, because we have been schooled to recognize and evaluate them.

So in petrositis. The time is ripe for a concentrated study of the entire clinical picture, for the determination of what constitutes a case of petrositis, for a clinical means to determine the site of the lesion in the petrosa, and lastly, what this paper concerns itself with, a portrayal of what indicates progression as contrasted with regression of the living pathology in the petrous perilabyrinth.

The expression "living pathology" is used advisedly. It indicates, for us clinicians, a picture of a vital process, an active propelling phenomenon which stands in sharp contrast to the "terminal pathology" found at autopsy. So, with the aid of clinical observation there must be produced in one's mind a moving picture of the pathology in the patient who presents symptoms of petrositis. The surgeon is able to do this with no difficulty in acute suppurative appendicitis. The internist is no less capable in ascertaining the progress of a pneumonia. We otologists are able to judge almost to a nicety the progressing and regressing pathological stages of an acute purulent tympanomastoiditis *from clinical observation alone*.

To begin with, it is felt that the knowledge of the entire subject will be advanced by a wedding of Kopetzky and Almour's "osteitis" and Eagleton's "osteomyelitis." With William's statement to the effect that the two usually occur simultaneously in the petrous bone where air spaces and marrow spaces are situated side by side, there can be no exception taken. The term "osteomyelitis" of the petrous bone should be reserved for those cases, usually occurring in infancy, which so adequately have been described by Ramadier. It is suggested that "coalescing petrositis" be used as a descriptive clinical general term embracing the several anatomical and bacteriological forms of the disease as they occur in the living, leaving to the pathologist his own terminology. "Coalescing" is preferable to "coalescent," since the former suggests a continuous process, whereas the latter indicates a completed lesion.

Confronted at the bedside with a given case wherein signs and symptoms of petrosal involvement are evident, one must determine what course to pursue. From personal experience and from the

experience of others, subjective signs and symptoms may appear (1) Prior to the development of a suppurative mastoiditis, (2) Concomitant with the clinical recognition of a surgical mastoiditis, (3) After a simple mastoidectomy has been performed for the relief of a purulent mastoiditis.

With the comprehension of this, the recognition of the receding from the progressing case becomes simplified.

1 Where the pneumatic spaces in the mastoid process as yet show no involvement, as evidenced by otoscopic and roentgenological examination, and where some of the general signs of petrositis appear, such as eye-pain and narrowing of the palpebral fissure, they should be viewed in the same light as we look upon the presence of mastoid pain and tenderness in the earliest stage of an acute purulent otitis media. All of us know, too well for repetition, that an inflammatory reaction occurs in the mastoid cells with every case of acute purulent otitis media, and that it is present from the onset of the lesion. The tenderness over the bone, the pain frequently complained of, the x-ray evidence of clouding, and the fundamental histological studies of Schiebe, are adequate proof of this. Why not make use of this data now to explain the symptoms of first branch pain in the early stages of an acute otitis purulenta as the result of inflammatory reaction in the pars petrosa without coalescence having occurred?

With the establishment of drainage from the middle ear however, these symptoms should subside gradually, just as the tenderness over the mastoid process gradually disappears following myringotomy. Where the symptoms increase in severity, where an abducens palsy appears, where transient vertigo, nausea, and vomiting or facial palsy is complained of, a coalescing process and an advancement of the lesion is denoted. A simple mastoidectomy becomes indicated for drainage and exploration. A simple mastoidectomy, since the lucid description by Whiting, has carried within its meaning a complete exenteration of all diseased structures reachable through the operative approach. No one has had the temerity to allude to what we call the "simple mastoidectomy" as a "mastoidozygomatico-occipito-squamosectomy," but that is what we do. Then why not include in its meaning, and in its performance, the removal of all diseased tissue in the field of operation. It should be done in every instance, since a coalescing petro-

sitis involving this exposed area can and most often will produce an inflammatory reaction in the rest of the perilabyrinth, with all the basic signs of the lesion. The fact that this procedure very often is successful in affording a cure in *these types of cases* has given rise to the conception that all types of petrositis respond to the complete simple mastoidectomy.

Where symptoms continue unabated following the complete simple mastoidectomy further progression of the lesion is denoted, and additional surgical measures are required if a cure is to be obtained while the lesion is still intrapetrosal, and before it has ruptured. Recession is evidenced by a gradual lessening of all symptoms present.

2 Where the signs and symptoms of coalescing petrositis appear concomitantly with the development of a surgical mastoiditis, a simple mastoidectomy is indicated principally for the relief of the suppurative mastoiditis. In the course of the operation, search should be made for a fistulous opening in the portion of the petrous bone exposed by the surgery. When found, this should be enlarged and drained. Diseased cell tracts should be followed and eviscerated. Recession of the petrosal lesion in these cases is evidenced by an almost immediate diminution, usually within thirty-six hours, in the intensity and duration of the pain, no matter where located. The otorrhea subsides, and no transitory symptoms due to involvement of the intra- or juxtapetrosal structures appear. Progression of the lesion is to be suspected when the clinical findings persist and are augmented. Further surgery then becomes necessary.

In both of the above categories the x-ray picture plays an important role. The findings on the x-ray films should be interpreted, *first*, as an individual factor giving information of the status quo, and *second*, in comparison with films previously taken of the same patient, affording information of the moving pathology. Where only clouding is present, and where halisteresis and cell coalescence is absent, and in successive films this status is maintained, one can expect recession of the lesion providing these findings are in accord with the clinical observations. Where some evidence of beginning halisteresis or of even localized destruction of bony septa is present, but upon successive plates this has not increased, recession of the lesion can be looked for when this finding is associated with gradual improvement in the clinical picture. By this is meant a lessening in the intensity of the retro-orbital pain, a diminution of the otorrhea, and a marked improvement

in all symptoms pertaining to the neighboring structures that may be involved by a petrosal lesion. Where successive x-ray plates show an increase in halisteresis, septal destruction, and coalescence, a progression of the lesion is to be expected and adequate therapy instituted before the suppurative focus ruptures extrapetrosally.

It is not amiss at this point to caution against labelling every case showing clouding of the petrous portion of the temporal bone a case of "coalescing petrositis." Taylor has emphasized this. If we but apply our knowledge of the interpretation of mastoid films to that taken of the petrous bone, this error will soon correct itself.

3 In by far the greatest number of cases, signs and symptoms of petrositis make their appearance after a simple mastoidectomy has been performed for an acute surgical mastoiditis. Within a varying length of time postoperatively, some or all of the basic signs and symptoms make their appearance, often grouped with one or more of the localizing signs. It is in these cases, more so than in those of the preceding two groups, that the acute problems present themselves. In the first place, a differential diagnosis must be made from other conditions causing the same symptomatology. Secondly, a careful, mature, well-studied conclusion must be reached as to whether one is dealing with a coalescing petrositis which is in a stage of recession or of progression. Lastly, where one has succeeded in draining a focus in the petrosa by one or another means, one must determine whether the drainage afforded has been and continues to be sufficient for the cure of the lesion.

This paper does not concern itself with the differential diagnosis of coalescing petrositis. With the second problem, however, it can be said that regardless of what signs and symptoms may be present, regardless of what significance they may have in localization of the lesion in the pars petrosa, the differentiation between a case of coalescing petrositis which is in the process of regression and one which is progressing rests upon the close, almost hourly observation of the transitory changes in the clinical picture presented. Not only your own findings, but the nurse's notes and her comments, and the patient's statements and reactions to his surroundings must be given the most careful consideration and study. Nothing is too trivial to be passed over lightly.

It is very difficult to put into words what is ordinarily termed "clinical intuition." In addition, not all of the cases of coalescing petrositis present an identical symptomatology. Consequently, at the risk of being termed didactic your essayist attempts to list the salient factors, all of which can occur in this disease either separately or in conjunction with one another that may help in distinguishing a recurring from a progressing lesion.

PROGRESSION should be suspected—

1 When the symptom of pain, wherever located, but predominantly referred to the distribution of the first branch of the fifth nerve increases in severity and duration, loses its nocturnal character and occurs also during the greatest part of the day, changes from a localized symptom to become more general in its distribution, *suddenly* disappears. The latter, from personal experience, is a grave sign indicating a rupture through the petrous bone.

2 When the otomastoidal discharge continues to be profuse, or *suddenly* ceases. In the latter instance one should suspect a rupture into the lateral pharyngeal spaces.

3 When transitory phenomena make their appearance

- a A transient facial weakness
- b A transient dizzy spell, not actual directional vertigo
- c Transient vomiting and nausea. These are not projectile in character, and are most often attributed to a "spoiled stomach" by the parents
- d. When an exhaustible ankle clonus, not previously noted, makes its appearance.
- e. When photophobia is complained of

4 When a homolateral abducens palsy occurs after other signs and symptoms have enabled one to make the diagnosis of coalescing petrositis.

5 When an abducens palsy, which was present prior to the performance of a simple mastoidectomy, fails to show improvement after this surgical measure has been instituted.

6 When evidences of involvement of the ninth, tenth, and eleventh nerves become manifest.

7 When signs of meningeal irritation appear.

8 When the patient becomes increasingly irritable, refuses the attentions of his nurse and family, and "wants to be left alone."

9 When the patient begins to look sick.

This must be given the same value that we attribute to it when estimating the progress of a mastoidal infection

These last two elements are of the utmost importance, and yet it is almost impossible to put the weight of their significance in words

REGRESSION can be expected—

1 When the pain, wherever located, *gradually* diminishes in intensity and duration, the patient has increasingly longer intervals of sleep and freedom from pain

2 When the otorrhea *gradually* lessens in amount

3 When *no* transient phenomena due to the irritation or involvement of the intra- or peripetrosal structures appear

4 When an abducens palsy, if present, shows signs of improvement.

5 When the patient "begins to look better," and takes an increasing interest in his surroundings

Further consideration must be given to those cases wherein progressing coalescing petrositis has been diagnosed, and wherein further surgery, regardless of its classification, has been instituted and drainage of the focus has been obtained. A fistula or diseased cell tracts may have been drained through the previously performed simple mastoidectomy, or a radical mastoidectomy may have located and drained the antelabyrinthine area. Nevertheless, the clinical picture continues unchanged or is added to by other symptoms. The x-rays here, with the possible exception of the Stenver's position which may reveal a rupture into the middle fossa, no longer help one. The pain continues or *suddenly* ceases. The abducens palsy fails to show improvement within twenty-four to thirty-six hours. Most important of all, the patient is still sick—he *looks* sick and he *feels* sick. It is at this stage that one must further attack the petrous bone if intracranial complications are to be avoided

The success of a fistula drained or of diseased cell tracts removed is soon apparent in the more than gradual improvement in the clinical picture. The failure of this to improve should not deter one from utilizing every means at his disposal to effect a cure. We have in our hands today tools to cope with every conceivable form of petrositis. Each has its use, and there remains only the intelligent comprehension of their use—how to use them, if to use them, and most important of all, when to use them.

A word should be said concerning the asymptomatic cases of petrositis. We are all familiar with the symptomless type of acute mastoiditis which occurs in diabetes, in the presence of other debilitating diseases, or is caused by the pneumococcus III and Friedlander's bacillus. These factors play their same roles in petrositis, and we must be guided in recognizing them by our clinical and roentgenological observations if we are to hope for any degree of success in overcoming these formidable types of infection when they occur in the petrosa.

This paper is offered as a "feeler," based as it is mostly upon personal observations. However, since no one as yet has attempted to formulate any criteria to guide us in differentiating between the regressing and progressing cases of *true* coalescing petrositis, let this paper be the first offering. Even though these remarks may be termed didactic, if they stimulate all of us to a broader view—a definite view,—instead of futile and sometimes destructive generalizations, this paper will have served its purpose,—especially so when the mature opinions and conclusions of others will have added to it, and, it is sincerely hoped, will have augmented the observations here presented.

Young doctors in civil life throughout New York, New Jersey, and Delaware will have opportunity to compete for appointment as first lieutenants in the Medical Corps of the Regular Army in examination Sept 13 to 17, it is announced at Second Corps Area headquarters

A year's internship is an approved hospital is required. Candidates must be male citizens and not more than thirty-one years, nine months.

Interested physicians may obtain information and application blanks from Adjutant General, Governor's Island

NON-POLLEN INHALANTS IN HAY FEVER

A Study of Their Part In Its Symptomatology

HARRY S. BERKOFF, M.D., *New York City*

Chief of Allergy Clinic, City Hospital, Physician, New York Hospital, O.P.D.

An explanation that has from time to time been offered to those who are confronted with the increasing symptoms and complaints of hay fever patients as the season progresses is that factors other than pollen influence the results obtained.

The diagnosis appears to have been correct, the dosage of pollen extract, adequate and potent, administered preseasonally and well into the season, the tolerance of the patient satisfactory, exposure reduced to a minimum, yes, even to the extent of partial imprisonment in a mechanized atmosphere—and yet, the result no better than in an untreated season. This has been observed in several consecutive years so that the factor of varying pollen concentration has been eliminated. What explanation is there, if any, for the poor results, estimated at from 91 to thirty-six per cent on the part of the country's ablest allergists?

Walker¹ in 1921 suggested that "fruit, bacteria, and exposure to olfactory irritants" may aggravate the symptoms of hay fever. Later as the scope of suspicion extended, other workers²⁻⁷ sought to indict various other inhalants, such as dust, animal danders,orris, foods, other pollens, nasal pathology, etc. Hyposensitization with these wherever possible or elimination from the environment, dietary restrictions, vaccinotherapy—all have been reported as helpful adjuncts to pollen therapy for hay fever. Reports of large series statistically are not available. One is led to wonder, therefore, if the recently increased popularity of the chemical and mechanical methods in the approach of this condition is not a reflection upon the actual status of our therapy even when all extraneous factors have been taken into consideration. Who has not confronted patients with progressive allergic disturbances, coming from the best clinics or the most capable al-

lergists where for years they submitted to treatment with little, if any, improvement?

It was in an effort to evaluate the part that nonpollen inhalants may play in the aggravation of hay fever that for the past four years (1933-1936), the patients of a hay fever clinic conducted in a large department store, have been asked at the end of each season to indicate on a questionnaire whether in their opinion the following list of substances appeared to aggravate their symptoms during their particular season.

Dust	Perfumes
Powders	Fumes (chemical)
Woolens	Tobacco smoke
Cotton	Cooled air (5 floors)
Paints	Soaps

One hundred forty-nine patients are included in this survey (ninety women and fifty-nine men) from nineteen to sixty years of age, in occupations ranging from porters and packers on substreet levels through the salespeople on the diverse merchandise floors, rich in their inhalant atmosphere, to the clerical workers in the offices. The usual pre- and coseasonal method, after intracutaneous testing, was pursued in the three groups sensitive to trees, grasses, or weeds, in an effort toward maximum dosage under the circumstances. The years of treatment this group received was as follows:

	<i>Patients</i>
4 years	33
3 "	23
2 "	28
1 "	65

During this time a total of 319 replies, equivalent to seasons of treatment received, was obtained with an accompanying expression of the estimated percentage of improvements in symptoms, if any.

Table I summarizes the numbers of patients claiming aggravation of symptoms by the various factors listed in the questionnaires.

It will be seen from this table that the one factor of significance in the aggravation of symptoms (stated in forty-one per cent of the replies) appears to be dust. The other substances listed were involved in from two to eleven per cent of the cases and would seem to be of even less importance when we remember that our clinic group returned to its daily occupations after a brief rest period following treatment and that its opportunities for exposure to the various non-pollen inhalants mentioned must have been vastly greater than those of the outside population. Its members gathered from such extremes of environment as the sub-basement mechanical departments, the stock bins, offices, garages, cold-storage vaults, sales floors, to the shops on the roof top. The very fact that so few of this diverse group were impressed with their exposure to the nonpollen inhalants or believed in their importance, even when it was suggested to them, would derive added significance.

In analyzing further the question of dust sensitivity it was noted that there was a definite variability in the replies from year to year as to its aggravating quality in a considerable number of patients. Thirty-three claimed that dust was not a constant factor during their years of treatment. Of this number eleven were treated for three and four consecutive seasons and in only one of these did they believe dust to be an aggravator, nine were treated for a similar period with dust as an alleged factor in but two seasons. Forty-two other patients noted dust in each of their treated seasons but it should be stated that twenty-two of this number were observed for only one season.

In Table II is shown a list of twenty-five patients in whom it was interesting to see the relationship between skin sensitivity to dust, presence or absence of clinical aggravation of symptoms by it and the degree of improvement as a result of hyposensitization by pollens alone. The reaction indicated by ++ would comprise wheal about $1\frac{1}{2}$ cm in diameter, with varying pseudopodia, and surrounding erythema of three or more cm in diameter—in other words, a well-marked reaction. The cases selected represent all those which had a

skin reaction of at least this degree during any of the treated seasons.

Half of this group, admittedly aggravated by dust and showing a marked skin reaction to it, still derived seventy-five per cent and more of improvement under simple pollen therapy, with no opportunity for avoiding dust exposure.

In a group of seven patients who showed a similar skin reactivity to orris root, only one admitted aggravation of symptoms by it and the majority had seventy-five per cent relief of symptoms with pollen therapy.

Skin tests would seem, therefore, to have disproven themselves once more as a dependable guide either to the clinical importance of the inhalants in question—dust and orris root—or to the expected results of therapy which does not include them in its scope.

The result of treatment (pollen) in those who for one or more years reported aggravation by dust is shown in the following:

Percentage improvement	More than 75%	75%	50%	25%	0%
Patients	18	41	8	12	0

Discussion

In view of the rather high percentage of unsatisfactory results from so-called preventive hay fever therapy and the explanation offered by numerous workers that inhalants other than pollen may be the aggravating factors responsible for this, it seemed desirable to survey this question from a practical, clinical standpoint. A group of 149 employees of a large department store, comprising a hay fever clinic that offered ample opportunity for inhalant exposure, was asked to indicate on a questionnaire at the end of each of four consecutive seasons of treatment whether a given list of the most common inhalants appeared to aggravate their symptoms during the particular season. There are, of course, the usual objections to this method of securing data and making any deductions therefrom, but since no more exact or inclusive measure of such symptoms as constitute hay fever exists and much of our previous information is based on it, we must of necessity resort to it. This much should be added, that the intel-

ligence of this group and the requested care taken in the answering of the questions was undoubtedly of a much higher order than that of the average clinic patient.

Dust alone from the standpoint of numbers, appeared to be an aggravator of symptoms. It was mentioned in forty-one per cent of the replies, equivalent to seasons of treatment. Powders and tobacco smoke were next, each with about eleven per cent frequency. The other inhalants were involved in numbers so small as to make their significance very questionable.

When the factor of dust was further scrutinized the following was revealed:

- 1 The inconstancy of its aggravating tendency from year to year in the same patient
- 2 Progressive improvement on pollen therapy in successive years although dust was reported as an aggravator
- 3 Lack of correlation between skin sensitivity to dust, its symptom-stress, and the therapeutic result with pollen only
- 4 Three-fourths of all those reporting dust as a factor in one or more seasons obtained seventy-five per cent or more of improvement in their symptoms on pollen therapy

Finally, with reference to dust, it may be well to remember that the constituent in it most responsible for the added effect ascribed to it may after all be pollen, enmeshed, concentrated, and more scaterable.

A number of studies have appeared recently concerning controlled atmospheric conditions in the alleviation of hay fever. While the number answering the question with regard to cooled air in this survey is too small for any deductions, it is interesting that almost as many felt the cooled air, which was supplied to five of the selling floors, intensified their symp-

toms as those who believed themselves benefited by it.

The problem of foods has not come in for special observation in this study. It may be mentioned, however, that their part in the symptomatology of hay fever has not been impressive and no case due primarily to foods has come to our attention.

If the conclusion that these observations have led to is correct, that the role of nonpollen inhalants in the symptomatology of hay fever is negligible, with the possible exception of dust as a factor apart from its pollen content, it is presented in an effort to encourage a re-evaluation of some of our accepted notions in regard to our therapy. In the words of Thommen it is "not an easy task to assign an adequate reason to the failures of pollen therapy. The reason for this may remain unknown till the exact mechanism of protection is ascertained and the offending pollen sub-

TABLE II

	Skin sensitivity	Symptoms aggravated by dust	Results
B. K.	++	Yes, each of 4 seasons.	Had almost 100% relief in last 3 seasons.
S. O.	++	No	75% improved.
C. R.	+ ± (35) ± (32)	Yes, but in only one season of treatment.	50% imp'd. that season 75% the next two and only 25% the last
F. S.	+ ±	Yes during 2 of 3 treated seasons.	75% imp'd.
B. S.	+ ±	No. Works in clothing dept.	75% imp'd.
B. T.	++	Yes during 2 of 4 treated seasons.	Last 2 seasons 70% imp'd.
M. W.	++ (33) + (35)	Yes during all 4 seasons.	25-50% imp'd.
M. Z.	++	Yes, in 3 of 4 treated seasons.	75% imp'd.
A. G.	++ (32) + (35)	Yes, during 3 treated seasons.	75% imp'd.
C. S.	+ ±	No. Treated 3 years.	50-75% imp'd.
J. B.	++ (32)	Yes once in 3 treated seasons.	50% imp'd.
A. C.	++	Yes in 2 of 3 seasons.	Up to 90% imp'd.
C. E.	++	Yes, in 1 of 2 seasons.	75% imp'd. Also had asthma.
M. M.	++	No. In 2 seasons of treatment.	50% better first none second year
P. B.	++	Yes during 2 seasons.	75% imp'd.
A. D.	++	Yes, one season.	75% imp'd.
C. K.	++	Yes, one season.	90% imp'd.
N. K.	++	No	75%
C. McQ.	++	No	90%
C. P.	++	Yes one season.	75%
N. B.	+ ±	Yes during 2 seasons.	25-50% better
M. B.	++	No. Treated 4 seasons.	25-50%
F. C.	+ ±	No	Up to 90% imp'd.
J. C.	++	Yes, during all 4 seasons.	50-75% imp'd.
A. H.	— (32) ++ (35)	Yes during all 4 seasons.	No improvement.

TABLE I

	1933	1934	1935	1936	Total
Dust	33	29	38	32	132
Powders	14	7	8	8	37
Woolens	3	6	6	4	19

THAT MATERNAL DEATH-RATE IS DROPPING

The lowest number of deaths of mothers at child-birth in any year is indicated for 1937 on the basis of maternal mortality records of the New York City Health Department for the first seven months of this year

Back of this record is a local drive by the medical profession and the Health and Hospitals departments, which as yet has hardly begun to bear fruit.

According to an interview in the *New York Evening Post*, Dr George Kosmak, secretary to the Advisory Obstetric Council to the Health Department, believes the slightly lower rate negligible compared to what he hopes eventually may be achieved

The maternal mortality rate is based on per thousand live births

For the first seven months of this year this rate was 4.4 deaths, compared with 5.0 in 1936 and 5.6 in 1935 for the same period

Except during the deep depression years of 1931, 1932, and 1933, when an average of six per thousand was recorded, this rate has remained constant for almost twenty years, ranging slightly above five deaths per thousand live births

"Even though 1937 should show a slightly lower maternal mortality rate, really demonstrable achievement is still to be realized," Dr Kosmak said

"A great deal has been done in the field of prenatal care, but if we are really to lower maternal mortality the emphasis must be on proper care during labor This is still the most important problem

"A better viewpoint has been reached by prospective mothers and doctors who have come to realize that a painless birth is not necessarily the safest for herself or the child"

Dr Kosmak declared that better handling of obstetrical cases and higher standards of hospital service remained a great need

The excessive use of anesthetics and operative technics to hasten labor is lessening, he said, with both patients and doctors realizing that normal, spontaneous delivery should be relied upon wherever possible.

The most recent large-scale analysis here showing mode of delivery was in 1933 In 21,000 births, almost one-fourth were deliveries aided by operative technic

In this study, the large public hospitals reported the highest proportion of normal deliveries, averaging about ninety per cent Some of the private maternity institutions, many of them considered the fashionable place to give birth to a child, showed operative type of deliveries in fifty per cent of the cases

A new study is under way by the five county medical societies, under the auspices of the Advisory Obstetric Council, with the Kings County Medical Society preparing the most intensive maternal mortality study ever undertaken in any borough

This report is expected to be ready late in the fall

Some improvement of conditions in private maternity hospitals resulted last year when Hospitals Commissioner Goldwater was given enlarged powers in supervising these institutions under the present licensing law

A number of them were unable to meet the requirements set up by Department of Hospitals and were forced to close their doors

Despite these improvements, however, the Hospital Survey for New York last May stated that while there were more than a sufficient number of hospital beds for maternity care, the actual care and handling of a patient was far from the best

The report recommended "that more effective supervision be maintained by State and local authorities over small voluntary hospitals accentuating maternity patients, and over proprietary hospitals offering service to such patients, and that higher standards of professional care be required in both"

Improvement in this field has been slow, according to the report of the Hospital Survey, which carried most of the recommendations announced by Health Commissioner Rice two years previously

THE WARBLE FLY—DERMATOBIA HOMINIS, LINN

Report of Two Cases Imported from Costa Rica

AARON SUMNER PRICE, M D, *New York City*

Clinical Professor of Pathology, New York Polyclinic Medical School and Hospital

Hegner¹ described three chief groups of flies invading man. The *Calliphoridae* or blow flies, the *Sarcophagidae* or flesh flies, and the *Oestridae* or warble and botflies. Most forms of the first two groups live in decaying meat and are found only occasionally as parasites. When they do invade man they have a tendency to feed on and destroy, with their powerful jaws, both the soft tissues and bone. If they are not removed the results may be disastrous to the host. The *Oestridae*, on the other hand, normally pass their larval stage as parasites, and they seldom cause the death of the host unless they are present in undue numbers or else situated in some unusual location. Dunn² reported a case of perforation of the anterior fontanelle, with death of the baby, but this is unusual.

Various members of the family of *Oestridae* pass their larval stage in the skin, the nasal passages, or in the intestinal tract. The larvae live in the host where they may cause rather violent inflammatory reactions, but the parasite seems to live on the exudates rather than the tissues proper. Matheson³ and Stitt⁴ each give a detailed classification of the Diptera that are associated with human diseases.

Dermatobia hominis (Linnaeus, 1781) is a large bee-like fly that is widely distributed through Mexico, Central and South America. It is not found in the United States. The flies are seldom seen because they live chiefly in wooded and forested districts. They have very rudimentary mouth parts and for that reason are not themselves biting flies. These flies secure a carrier to play a role in the wide distribution of their eggs and larvae. The female of the species catches other flies or mosquitoes and holds them in her clutches until she has glued to the ventral surface of their bodies some twenty or more ova of her own. The carrier is then set free. One *D. hominis*

female may use four or five carriers, each bearing a cluster of her ova. The eggs mature while attached to the abdomen of the mosquito, or fly, so that when the carrier rests on the skin of the mammalian host the larvae within the eggs make their exit and are then ready for penetration of the host's skin.

From the variety of carriers that have been described, it is possible that the female is not as particular in selecting the carrier as was once thought. Even the common house fly has been found to act in the carrier capacity. The most commonly used mosquito is *Psorophora* (*Janthinsoma*) *lutzii*, Theobald, which has been described as a vicious biter. Dunn,⁵ however, described a personal experience in which he found the eggs on a fly of the anthomyid type (*Species* *Limnophora*)—which is not a blood sucker—and decided to find out definitely whether this *Limnophora* fly was acting as a carrier for *Dermatobia hominis*, or some other species. The ova were found in a stage where the opercula (lids) of the eggs were loose, and the larvae ready to emerge. Two of the larvae were placed on his forearm, and with a hand lens he observed them to slowly penetrate the unbroken skin and bury themselves. Prior to this observation, it was presumed that the larva always entered through the bite caused by the carrier. Much to Dunn's amazement, and later discomfort, he found that he was harboring four additional larvae in other locations. Nevertheless, he permitted all to mature and found that within forty-six to fifty-four days the larvae emerged as full grown. He then incubated them in moist sand, since the pupal stage is usually passed in the ground. The full grown flies emerged from the pupal stage in from twenty-two to twenty-four days.

At first the entrance of the larva may not be recognized, but soon a pimple develops which gradually forms a warble,

or boil. In the central area, there is a small opening which discharges considerable serous exudate, and through which the tip of the larva protrudes so as to breathe through the spiracles in its posterior extremity. It shows early a series of rows of spines, or hooklets, which help to keep the larva anchored. The spines are short, stout, and directed backward. They probably, also, aid the larva in shifting its position. From time to time,

for several days. In cattle the larva fall to the ground where they will pupate. Healing of the lesions occurs within a few days after the emergence of the larva, and usually there is no permanent damage other than a small pigmented or depigmented scar in the skin.

Case Reports

CASE 1 A young Spanish male came directly from the boat to enter New

Fig 1 Second stage larva of *Dermatobia hominis* (ver macque) 10 X

Fig 2 Larva of *Dermatobia hominis* 3 X.

the tip end seems to be busy, working in and out through the skin, pushing away the old exudates. At first, the larva has an enlarged club-shaped head, with the club buried (ver macque stage). Moulting takes place about the tenth or twelfth day. The larva grows until it is more or less blimp-shaped and covered by small spines (torcel stage). The second moulting takes place about the twenty-second to twenty-fourth day. The moults are pushed out through the pore, or sinus opening. At these times, the parasite may be very annoying, due to its activity.

Projecting hooks or barbs at the posterior extremity are used at various intervals to rasp the margins of the sinus opening and clear it of encrusted exudates. This rasping activity may be particularly noticeable for several days preceding the emergence of the larva. At the proper time, the larva seems to pop out, rather unexpectedly, after having seemingly made trial and partial exits

York Polyclinic Medical School and Hospital on the private service of Dr. T. J. Tobin. He complained of edema, pain, and swelling of the upper right eyelid which had increased in severity throughout his trip from Costa Rica, by way of Puerto Rico, to the United States. The lesion was of several weeks duration. He was unable to separate the palpebral margins because of the edema. A definite small pinpoint-sized sinus opening was present which exuded a small amount of serum. The immediate area surrounding this was red and indurated. Hot poultices were applied without softening the area. A small incision was made and a shiver-like body about six mm in length, presenting a dark colored knob at the buried end, was removed. Healing occurred promptly and the edema disappeared in several days.

The body removed from the eyelid was brought by the nurse to the laboratory. An enlarged photograph of the ver macque stage is shown (Fig. 1). Numerous small spines may be seen over the head end. The softer and lighter colored undeveloped body

was directed outward. Later, the patient stated that he probably acquired his parasite in Costa Rica, prior to sailing.

CASE 2 The second larva was brought to the laboratory for identification by Dr Angel Golderos. His patient gave the history that he had been hunting in Costa Rica. A "wicked" mosquito bite was obtained in the upper right thigh above the boot line. Later a warble developed. He came to the United States by way of Puerto Rico. Whenever the patient was on land, the lesion itched like "fury." However, as long as he was on the sea, the area caused him little disturbance. Immediately on landing in Puerto Rico, and again in the United States, the itching commenced. (Usually these lesions itch or pain worse at night.) The patient expressed the belief that the salt air had something to do with the relief from itching, although it is likely that the lower temperature on the sea lessened the activity of the parasite. The patient passed through the hands of six different physicians, all of whom prescribed poultices and ointments to hasten the ripening of the boil. Dr Golderos found a large, painful, indurated, and reddened abscessed area which was exuding a serous exudate through a small sinus opening. A dark body could be seen moving in and out at the opening. An attempt was made to grasp this dark body with forceps, but immediately the parasite retracted out of view when the area was touched, only to reappear as soon as the forceps were taken away. Regardless of the speed used in the attempts to grasp the dark object, it was gone into the tissues in a flash and was out of reach. Pain prevented extensive probing or gouging. Dr Golderos "finally" realized that this object was probably some form of tropical parasite, and he logically reasoned that cold might do it damage. Ethyl chloride was used to freeze the area. The following day the patient returned to have the dead larva easily removed with the forceps. The wound healed rapidly with all signs of inflammation receding in about five or six days. Photographs of this almost mature larva show that it probably would have escaped of its own accord within a few more days. It is estimated that the patient had

carried the larva about forty-three days (Fig 2)

Although Mook⁶ has previously reported a case in a patient coming from Yucatan little more need be said, since the infestation is not primarily a lesion found in the United States. In the countries where the fly is found, the damage to animals is definitely of economic importance. When cattle are heavily infested they lose weight, become sickly, and are covered with warbles. Their hides may be completely ruined for commercial purposes by the number of holes produced.

Cattle, horses, donkeys, mules, cats, and dogs, as well as wild animals and man, may be infested. It is believed by Navarro⁷ to be especially prevalent near the eucalyptus trees and forests in Sao Paulo, Brazil, and Dunn⁵ reports the disastrous financial loss to the government of Panama, which tried to encourage cattle raisers.

Native treatment consists chiefly of poisoning the larva with tobacco juice poultices and then squeezing, others have incised and then squeezed out the larva. Generally, the latter procedure is too painful without first killing the parasite. Stitt⁴ recommended injection with phenol or chloroform. Matheson's suggestion of freezing, before squeezing out the larva was improved upon by Dr Golderos by first killing it by freezing and then merely lifting out the larva with the forceps at a later time.

ANNUAL CONFERENCE OF COUNTY SOCIETY SECRETARIES

Announcement is made that the Annual Conference of County Society Secretaries has been called for Wednesday, September 15 at 10 A M at the De Witt Clinton Hotel, Albany

PETER IRVING, Secretary

COLLAPSE COMPLICATING VARICOSE VEIN INJECTION OF SODIUM MORRHUATE

EUGENE F. TRAUB, M.D. and WILLIAM B. SWARTS, JR., M.D., *New York City*
From the Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital,
Columbia University

In the routine practice of treating varicose veins, one often overlooks the fact that dangerous complications may occur in addition to the minor troubles such as pain at the injection site, phlebitis, periphlebitis, and sloughing. We all fear the possibility of a thrombus breaking off and giving rise to pulmonary embolus, fortunately, however, this is a very rare occurrence.

In the last four years, there has been an increasing number of reports of cases which have had allergic-like reactions following the injection of a five per cent solution of sodium morrhuate for the obliteration of varicose veins. Zimmerman of Chicago was the first to report these allergic-like reactions. He reported four cases, two of which had systemic reactions which were allergic in character and were characterized by weakness and dizziness. These two patients did not lose consciousness and the reactions only lasted about one hour. The other two patients had allergic skin manifestations.

It was noticed by Zimmerman that the patient in whom the reaction was most severe had received numerous injections each week or every second week and then had a "rest or lapse period" of seven weeks before receiving the injection which gave her the anaphylactoid reaction. This time interval seems most important and the greatest care should be practiced when more than the usual time is permitted to lapse between treatments.

The intradermal test can be used to test for sensitivity but as yet the practicability of this procedure has not been proved. Zimmerman also reported reactions following the initial dose of sodium morrhuate. It is evident that care and small dosage should be the rule for the first injection. The reason the offending substance cannot be very well studied by the usual intradermal tests is that the solution is essentially an irritating mixture to promote thrombosis and subsequent fibrosis and obliteration of the ves-

sel lumen. The skin of normal people reacts positively to diluted solutions of sodium morrhuate so that attacking the problem with our usual methods is of doubtful value.

Praver and Becker² observed sensitization phenomena in three per cent of the cases in a large clinic where sodium morrhuate was the sclerosing solution. They divided the complications into cutaneous and nutritoid. It was recommended that an immediate change should be made in the solution used when allergic-like symptoms developed. Allergic testing also failed in their hands for the above reason.

Lewis³ recently reported a severe state of shock following the injection of five per cent sodium morrhuate from which the patient recovered in five hours without requiring hospitalization. The cardiovascular collapse which was noted in his patient is interesting when compared to the cases we are citing. An urticarial skin eruption was present with systemic reaction.

Case Reports

CASE 1 J. H., female, aged fifty-eight, appeared October 16, 1935 at the Skin and Cancer Unit of the New York Post-Graduate Medical School and Hospital with a varicose eczema of both lower legs. Since she had many varicose veins, it was felt that obliteration of the veins with diminution in stasis edema would benefit the skin eruption. Beginning that date she received 25 c.c. of five per cent sodium morrhuate which was continued at about two week intervals for a total of ten injections, the last of which was given on February 26, 1936. She returned May 20 and received another injection with no ill effect.

The varicose eczema so improved during the summer that she stopped treatment, but she appeared September 21 in the clinic with a slight recurrence of the varicose eczema. Again it was felt that the skin condition would be improved by the further obliteration of the remaining varicosities. Accordingly she was given 25 c.c. of

five per cent sodium morrhuate and about one hour later, on her way home from the clinic, she felt so weak and dizzy that she was compelled to sit on the street curb for thirty minutes before proceeding home.

She did not report to the clinic her spell of dizziness, and returned for another injection of 25 c.c. of sodium morrhuate September 30. No immediate reaction followed, but the next day she felt so very weak and nauseated that it necessitated her going to bed for two hours. She said later that she did not feel like herself for two days.

Still not reporting her previous complications, she came for another injection October 21, and received the usual 25 c.c. of five per cent sodium morrhuate. Immediately after this injection, the patient passed instantly into a deep comatose state, became very cyanotic, and pulseless with much foaming at the mouth. The pupils were contracted. As quickly as possible, 15 c.c. of 1 1000 adrenalin was given, together with 0.5 gram of caffeine sodio-benzoate. No improvement was noted in condition and she was rushed to the hospital ward.

Because of very evident cardiovascular collapse and difficult breathing, an intravenous solution of ten per cent glucose in normal saline was started and 1000 c.c. allowed to run into the patient. She was also given 0.5 gram of caffeine sodio-benzoate with $\frac{1}{2}$ c.c. of 1 1000 adrenalin every half hour. Projectile vomiting was present. It was not possible to obtain a blood pressure reading. The patient remained in deep coma with signs of severe shock and impending death for $2\frac{1}{2}$ hours. Very gradually, she regained consciousness and complained of very severe headache. Water could not be retained for five hours because of marked nausea, and prolonged projectile vomiting. Six hours after collapse, her blood pressure was 105/80.

The next day, the patient was so weak that she was compelled to stay in bed. Neurological examination did not reveal any paralyses, but just a generalized weakness. Since the patient had persistent, severe headache with projectile vomiting, the possibility of an acute cerebral vascular accident was entertained.

Two days later, she still complained of weakness and dizziness. Her blood pressure rose to 138/78. There were no signs of any cerebral vascular catastrophe.

Four days after the collapse, she was discharged from the hospital. The general weakness and dizziness still persisted to some degree, but it was felt that she could recover her full strength at home as well as in the hospital.

No allergic history either in patient or in family could be elicited.

Laboratory studies on the urine were negative. The blood showed a leukocytosis of 12,700 with a normal differential count. No eosinophilia.

CASE 2 MM, male, age fifty-two, presented himself May 1933 for treatment in the varicose vein clinic of the New York Post-Graduate Medical School and Hospital. He had extensive varicosities with concomitant eczema on both lower legs which had been present for thirty years. There was no contraindication for injection therapy. Five per cent sodium morrhuate was selected for the sclerosing agent and he received three c.c. of the solution at the rate of two injections a month. A total of fourteen injections were given. The therapy was stopped in December because of marked improvement.

The patient was not seen again until October 10, 1936, approximately three years later. He had a recurrence of marked varicosities and an ulcer on the lower third of the inner side of his right leg. Injection therapy with two c.c. of five per cent sodium morrhuate was again started. A week later he received the same injection. He did not complain of systemic after-effects from these injections, but had considerable local pain which was not present when previously treated.

On October 31, the patient returned for another injection and was given two c.c. of five per cent sodium morrhuate. Shortly after the administration the patient felt weak and dizzy and very quickly lapsed into a state of deep stupor. Cyanosis and great respiratory difficulty were noted. The pulse was weak and thready. Foaming at the mouth was present. Fifteen minutes later, no pulse could be perceived nor could the blood pressure be obtained. Because of the great evident respiratory distress, oxygen was administered through a nasal catheter after the mucous was aspirated from the throat. Caffeine sodio-benzoate, adrenalin, and coramine were administered in quick succession. During all these procedures, the patient gave no signs of muscular activity except the very shallow breathing. In about forty-five minutes, there was some evidence of recovery and he was quickly taken to the hospital ward. A provisional diagnosis of coronary thrombosis was made.

It was not until two hours after the collapse that the patient regained consciousness. Intravenous solutions were not given because of the fear of coronary thrombosis. His blood pressure reading was 114/60.

An allergic history revealed that one sister has hay fever, but there never had been

any previous allergic episodes in the patient's past history

Urinalysis revealed no abnormal findings. Blood counts revealed no eosinophilia. Wassermann reaction negative.

Three days after the collapse, an electrocardiographic study showed no signs of coronary thrombosis.

On the third day after admission, patient was fully recovered and was discharged.

Comment

In Case 2, five per cent sodium morrhuate of a different brand was used which tends to exclude a particular make as being the cause of the collapse. This patient also had a series of regularly spaced injections followed by a "rest or lapse period" of three years. No systemic warning was given, but increased pain at the injection site was noted in the two injections proceeding the near fatal collapse following the third injection.*

The recorded accidents clearly establish that sodium morrhuate even when carefully given in comparatively small amounts is far from being a harmless compound. It would seem wise to entirely discontinue its use in such cases where the patient after having received a number of injections has a break in the treatment and then returns for further injections. Because such patients are the ones most likely to have a reaction, quinine hydrochloride and urethane or some other sclerosing remedy should be used to continue the treatment. Many of the other preparations seem to cause a little more local discomfort than does sodium morrhuate, but if after further experience they prove to be safer to use, it might be advisable to entirely discontinue the use of sodium morrhuate as a remedy for a condition which generally is not a serious one, hence the patient should not be subjected to any serious risk. We have found quinine hydrochloride and urethane a very excellent remedy for most cases and believe that this preparation might be given preference over sodium

morrhuate in the treatment of varicosities.

Conclusion

1 An increasing number of allergic-like complications are being reported with the use of five per cent sodium morrhuate as a sclerosing agent for the treatment of varicose veins.

2 Allergic-like reactions have occurred with the first injection of five per cent sodium morrhuate.

3 The most severe systemic reactions apparently are in those patients who have had previous injections of five per cent sodium morrhuate and after a variable "rest or lapse period" receive further injections to which they have become sensitized.

4 Reactions may be either cutaneous, systemic or a combination of both, in severity they may vary from slight urticarial skin reaction to states of shock so deep that immediate death is to be feared.

5 Before treating a new case a careful history as regards allergy in the patient or his immediate family or previous varicose vein injections of any kind is exceedingly important.

6 Patients should be asked specifically on their return visits concerning symptoms which may be interpreted as due to acquired sensitivity to the sodium morrhuate, i.e., dizziness and nausea. If such symptoms are elicited the injections should either be discontinued or the sclerosing solution changed.

7 Two cases* are reported in detail in which after a "rest or lapse period" of three months, the patients received three injections with increasing local or systemic reactions. The final reaction in each case was so severe that the patient was in deep coma for several hours and immediate death was feared.

*The authors desire to express their gratitude to Dr. A. Wilbur Duryee of the Medical Service in allowing us to publish Case 2. Dr. Duryee informed us also that he has recently seen three other similar cases in the medical ward of another institution of this city.

*Since this paper was submitted for publication, we have had a third case of collapse similar in all essentials to the two herein reported. Likewise a "lapse or rest period" again followed by the use of a single dose of five per cent sodium morrhuate resulted in collapse requiring urgent hospitalization.

LENGTHENING THE SEPTUM MOBILE NASI

A New Plastic Procedure

M WILLIAM MOOTNICK, M D, *New York City*

A thorough perusal of the literature on plastic surgery, fails to reveal an operation to cope with the following condition of a retracted columella. I, therefore, offer this original idea, in the hope that it may afford an outlet to this heretofore undescribed "bugbear" of the Rhinoplastic surgeon

This deformity may manifest itself in two degrees, as shown in Fig 1 and 2, illustrating a not uncommon nasal deformity. This plastic defect is usually seen, as a complication of rhinoplasty (Fig 1), where the nose has been unintentionally overshortened during the course of a plastic operation. Upon suturing the columella in place following this overshortening, find the columella retracted. Thus the nasal tip and the lower margin of the alae hang abnormally low. An attempt to correct this condition by a further shortening of the nasal

tip to the level of the retracted columella, would exaggerate the already existing condition. Fig 2 also illustrates the retracted columella with the alae hanging abnormally low.

The above mentioned conditions present a most unsightly deformity that is not only distasteful to the surgeon, but also to the patient.

It may also be the result of trauma, of abscess of the lower portion of the septum, or it may be a congenital defect.

The main objective, in this procedure, is to bring about a normal cosmetic arrangement of the nasal tip. Normally the columella is slightly lower than the alae, the former making an angle with the upper lip, known as the septo labial angle which should be between 90 and 105°, and the proper assembly of the combined structures should bring about the graceful curve which the nasal tip

Fig 1—Fig 2—Fig 3 Initial approach incision through columella—Fig 4 Elevating mucoperichondrial flaps. Lower end of septal cartilage exposed.—Fig 5 A B C D The three united incisions. E, Mucoperichondrial flap. H, D, Lower border of the septal cartilage.—Fig 6 F Exposed area of septal cartilage. G Sliding flaps lowered.—Fig 7 Technic of intranasal method. Flaps being undermined downward.

naturally possesses. This can be best accomplished by lowering the columella, which is the essence of this procedure, thus lengthening the septum mobile nasi, between the lower margin of the quadrangular cartilage and the external surface of the columella.

Procedure

An external longitudinal incision is made in the columella (Fig 3) and extended inwards to the lower end of the septal cartilage.
